## P R E F A C E.

---

IN the present edition of this work will be found a very large amount of new matter, most of which it is believed is calculated to throw considerable light on questions of importance, which have been engaging the public mind for several years. The greater part of pp. 1-101 is nearly the same in form with that of the first and second editions, while the matter in pp. 102-407, and pp. 531-606 did not appear in the earlier editions. A large portion of pp. 408-530 appeared in the first and second editions, and also in the thirteenth edition of "Observations on Odd Fellow and Friendly Societies," which is now out of print; but even a perusal of these pages will shew that they contain a great amount of entirely new data, having not only an important bearing on Friendly and Provident Societies, but on questions of serious importance in public Hygiene, and to which attention will be immediately directed.

The data from which has been deduced the expression for the general mortality of England and Wales, and which is used as a standard for the comparison of the results for sectional classes of the community, will be found in a condensed shape in Table B, page 4.

Throughout the whole of the three first papers, embraced in pp. 1-101, and more particularly in the Letter to the Registrar-General, given in pp. 13-15, the conditions under which sanitary investigations should be conducted are very fully discussed; and it is greatly to be regretted that the precautions pointed out are not more generally attended to in all such inquiries. It is perhaps impossible to point to any other investigations connected with the governmental departments of the country, in which less skill, judgment, and tact, have been evinced than in those bearing on the sanitary state of our large towns and cities; and hence the most unsatisfactory results of the vast amount of labour and enormous expenditure of money, particularly within the last dozen of years, without any improvement in the health of the population being effected. That the methods of investigation followed by those entrusted with the conduct of the sanitary

movement would be followed by no satisfactory result, was clearly foretold in the first edition of this work, published in 1845; and the same errors of method were also subsequently alluded to in the Reports of the Registrar-General himself; but not with that fulness, force, and urgency by which, from his important position and authority, no doubt, a powerful impression would have been made on the country, and thence on the departments entrusted with the regulation of sanitary measures. Relying on the evidence to be derived from the Returns of the Registrar-General, it would appear that the health of the country, instead of improving, is actually gradually deteriorating, and particularly so since the time the Sanitary Commissioners commenced to stir most actively in the health of towns. This fact is most strikingly exhibited by the following figures derived from the Returns of the Registrar-General.

The results in the second column of each section of the following Abstract exhibits the rate of mortality for males in England and Wales during the seven years 1838-44, and are derived from page 177 of the Registrar-General's ninth Report; and those in the third column are the corresponding results for the ten years 1845-54, and are taken from page xvi of his seventeenth Report.

The same figures will likewise be found in page 87 of the Appendix to the seventeenth Report. The last column of each section shews the excess of mortality per cent. in the more recent period of years.

*Rate of Mortality per Cent. per Annum in England and Wales during the Seven Years 1838-44, and the Ten Years 1845-54.*

| 85 ... 94       | 29.646         | 30.294         | 2.186                                   | 27.553         | 28.076         | 1.898                                   | 85 ... 94       |
| 95 and upwards. | 42.697         | 45.219         | 5.906                                   | 40.795         | 45.226         | 10.861                                  | 95 and upwards. |
| All Ages.       | 2.270          | 2.364          | 4.141                                   | 2.104          | 2.205          | 4.800                                   | All Ages.       |

It will be thus seen, that during the ten years 1845-54, the mortality for the male sex exceeds that for the seven years immediately preceding, by no less than 4.141 per cent.; and the excess for the female sex during the same period is as much as 4.800 per cent. These are results for which those who sanctioned the various sanitary movements which have agitated the country during the last thirteen or fourteen years were certainly not prepared, and it must be confessed that if the causes which influence the mortality taking place amongst the population of this country are within the control of the various Commissions and Boards which have, from time to time, been appointed for the superintendence of health, there must have been existing, during the last ten years, some unhappy combination of circumstances, which has not only neutralised the intended effect of any measures which have been carried out, but has added from four to five per cent. to the general rate of mortality which prevailed during the preceding seven years. It is of course not to be supposed that sanitary measures can be instantly carried out, and their effects immediately seen; but the period embraced in the preceding illustration is an extended one, and it would almost appear that, with the advance of time, the greater has been the rate of mortality amongst the population. It may be said that the period of ten years, in which this excessive mortality has taken place, embraces the epidemical years 1849 and 1854, in which cholera and diarrhœa raged so triumphantly; but even assuming that such epidemics are entirely beyond the reach of sanitary measures, and excluding those two years from the comparison, the remaining eight years of the period would still exhibit an excess of mortality of 2.511 per cent. for males, and of 2.947 for females. The following will afford a ready means of forming an opinion on this question:—

*Mortality per Cent. amongst Males at various ages in each of the Seventeen Years, 1838-54.*

| Ages.          | 1838.  | 1839.  | 1840.  | 1841.  | 1842.  | 1843.  | 1844.  | 1845.  | 1856.  | 1847.  | 1848.  | 1849.  | 1850.  | 1851.  | 1852.  | 1853.  | 1854.  | Ages.          |

| 95 and upwards | 49.699 | 43.112 | 48.498 | 46.633 | 46.427 | 45.681 | 43.228 | 49.035 | 51.651 | 56.607 | 42.435 | 42.859 | 38.560 | 41.937 | 43.422 | 47.305 | 38.382 | 95 and upwards |
| All Ages.      | 2.335  | 2.275  | 2.372  | 2.238  | 2.241  | 2.202  | 2.242  | 2.170  | 2.395  | 2.546  | 2.391  | 2.581  | 2.143  | 2.276  | 2.320  | 2.379  | 2.434  | All Ages.      |

It is thus evident that in the more recent years there is a general tendency to increased mortality amongst males; and like results will be observed in the following Abstract for female lives:—

*Mortality per Cent. amongst Females at various ages in each of the Seventeen Years, 1838–54.*

| Ages.           | 1838.  | 1839.  | 1840.  | 1841.  | 1842.  | 1843.  | 1844.  | 1845.  | 1846.  | 1847.  | 1848.  | 1849.  | 1850.  | 1851.  | 1852.  | 1853.  | 1854.  | Ages.           |

Whatever opinions may be entertained on the merits of the methods now being employed for the improvement of the health of towns, there can be no doubt that, so far as the returns of the Registrar-General afford the means of judging, the rate of mortality has been considerably increased in recent years. It is much to be regretted that the Registrar-General should not, in his Annual Reports, enter on a full discussion of this question, and endeavour to shew, from the ample body of facts in his possession, the changes which are from time to time taking place coincident with the presumed improvements introduced under the superintendence of the Board of Health, in the different districts of the kingdom. Certainly one of the main objects contemplated by the Registration Act is to pronounce, from time to time, upon the changes in the rates of mortality in different districts, and the causes to which they are due. Perhaps no other documents issued under the auspices of the Government are so pregnant with curious, and in many instances, important speculations; but the great problem as to the effect which the sanitary measures of the last dozen of years has had on the public health has been all but overlooked by him. The districts and sub-districts under the Registration Act enable him to determine, from year to year, with great nicety, the differences of mortality taking place within very limited localities; and as these districts can always with much precision, be connected with those in which the various measures are carried out by the inspectors and other officers of health, it is not too much to expect some distinct

information in regard to the actual influence those measures may have had on the mortality of the districts in which they have been in operation. With anything short of this, the public should not be satisfied. The Sanitary Commission is a most expensive one, and the country should be informed of the advantages derived from so great an outlay. Twelve years ago, a vast effort was made by an influential sanitary reformer, to shew that certain conditions, peculiar to some Metropolitan districts, produced the most wonderful destruction of human life as compared with the results of other districts; but it was subsequently found that the same data which led him to these conclusions did, when properly treated, prove the very opposite state of things to be the fact, and hence the caution needed in all such inquiries. As already stated, the Registrar-General has, in one of his Reports, noticed the fallacious methods of inquiry employed in the Health of Towns' Reports in question; but he is called on to go much further, for by virtue of his office he should interrogate the influence of all the measures carried out for promoting the public health, and should set forth in his Reports how far they have been successful or otherwise. Not only has the Parliament, but the people of this country, a right to the most ample and conclusive information on this subject.

The Registrar-General has for the first time in his Fourteenth Report attempted to throw some light on the influence of particular employments and occupations on health. The necessity of an inquiry into this question was pointed out to him in my letter of the 22nd March, 1845, see pp. 13-15 *seq.*, but while engaged in the preparation of that Report, he does not appear to have been aware of the remarkable illustrations of the influence of employments on health given in the previous editions of this work, as well as in the publication by Mr. Ratcliffe in the year 1850. It may also be here pointed out, that data derived from the sources from which the results in the following pages are deduced, as well as those appearing in Mr. Ratcliff's Analysis, are free from some objections to which the Registrar-General's Returns are unavoidably subject. Any one who is well acquainted with the condition and habits of the working classes must know how much more than usual those following some particular occupations are addicted to drinking and intoxicating habits, and therefore in viewing the general mortality of those particular employments, there is seen not only the mortality due to that branch of industry, but also the augmented ratio arising from indulgence in the too general habits of dissipation. The data collected from the records of Friendly Societies are however almost entirely free from such objections, for it is well understood that the working men who enter Benefit Societies and subsequently fall into irregular habits, soon after cease membership from inability to continue their periodical contributions to the club, and hence results deduced from observations made on those who maintain membership may be regarded as fairly indicating the relative degree of mortality to which those following various occupations are subject. In the following contributions a large amount of data is given not only on

that subject, but also on the ratio of sickness characteristic of different employments. From the observations contained in pp. 12-16, it will be seen that until the period of the next census in 1861, little reliance can be placed on the deductions made in the Reports of the Registrar-General in regard to the sanitary condition of different occupations. In page xxii of his Fourteenth Report he remarks that "the extraordinary mortality of butchers appears to have escaped observation," but on referring to page 94 of the first edition of this work, or page 411 *seq.*, it will be found to be distinctly pointed out that they experience a very high rate of mortality although not subject to above the average amount of sickness.

The Appendix to the Eighth Report of the Registrar-General contains a document of the highest value in throwing light on a question but indifferently understood at present, even by those giving much attention to vital statistics, namely, the great prolongation usually supposed to have taken place in the duration of life in this country within the last hundred or one hundred and fifty years.

The history of the progress of early inquiries made into the rate of mortality in different classes is too obscure to throw much light on this question, and it may therefore be sufficient to commence our observations on it from the period when the most active and successful efforts were made to impress on society the importance of having strict regard to well ascertained laws of mortality, in pecuniary transactions on life.

The honour of this great achievement in human knowledge belongs to the celebrated Dr. Price, and to the effect of his writings is mainly traceable the origin of the opinion, that in recent years the duration of life is much prolonged. The well-known Table of Mortality, usually, though erroneously, called the Northampton Table, and which is based on facts relating to the middle of the last century, exhibits a certain duration of life, and, for a long time, this Table continued to have undivided sway and authority in the estimation of writers and those engaged in assurance transactions, as indicating a near approximation to the rates of mortality among certain classes of the community.

At last, however, the late Mr. Milne brought under public attention the Table of Mortality, known as the Carlisle Table, and although the data embodied in it had reference to a period not much subsequent to the time to which the Northampton Table relates, still, from its more recent promulgation, the impression produced on the public mind was that which would naturally arise from other scientific writings, that each table represented the state of the science at a period near to the date of its first appearance.

The remarkably increased duration of life shewn by the Carlisle over the Northampton Table could not fail to arrest public attention, and the elaborate and able work in which Mr. Milne had issued his Table into the world claimed for it an importance and consideration not before conceded to even the labours of Dr. Price himself.

An examination of the writings of this period will at once satisfy any inquirer, that, a very short time after the appearance of Mr. Milne's work, the Carlisle Table began to grow in favour and public estimation, and hence, owing to the misconception that its recent appearance was evidence also of the recent origin of its data, and, owing to the increased duration of life deducible therefrom, an opinion prevailed that, since the appearance of Dr. Price's writings, an improvement had taken place in the public health. This impression has continued to gain ground until the present hour. It is consequently important to test the correctness of this opinion, not only from its bearings on legislative proceedings, but also from the remarkable hold which both classes of results have taken of the assurance interests of this country as well as of those on the Continent.

At first glance it must be evident that, from the almost cotemporaneous but remote origin of the data of both Tables, the observable difference in their rates of mortality could not be held to shew any improvement in the duration of life within recent periods ; besides, if a difference really does exist in their rates of mortality, that difference can be supposed to be only due to the local circumstances and influences peculiar to the small districts from which the data were collected, and, however true the results may be considered in regard to the district so represented by the data, it is impossible, from their evidence alone, to regard either as a type of the rate of mortality prevailing, at a former or the present period, among either the assurance classes, here or elsewhere, or as affording any evidence of the rate of mortality in the country generally, or in individual classes of the population.

Having said this much on the influence which the Northampton Table has exercised on the public mind, it is a very curious if not a mortifying circumstance to discover, at this advanced stage of our progress, that the gigantic monied interests of our greatest companies have long relied, almost exclusively, on a Table which has been falsely constructed, and which, in fact, does not represent the rate of mortality, even in the locality from which the data have been collected, nor, as will hereafter appear, the rate of mortality in the country generally, nor among the assured portion of the community.

As already stated, the Appendix to the Eighth Report of the Registrar-General contains one of the most valuable and interesting papers ever published in connection with the Northampton Table. Not only in an historical point of view, but also on account of its practical applications, the paper is one of first importance to life offices. To the author, Dr. Farr, the assurance interests of this country must be considered deeply indebted.

At the period when Dr. Price constructed the celebrated Northampton Table he did not possess all the elements necessary to determine correctly the rate of mortality in the locality under investigation, and, to supply the defective element, he had recourse to an hypothesis which recent inquiries have proved to be erroneous.

This should not be considered in the light of a reflection on Dr. Price, for there is reason to believe that, with the imperfect materials at his command, it would have been difficult to have followed a better plan than that which he adopted; but still Dr. Farr has been enabled to advance historical evidence to shew that the hypothesis was a fallacious one, and that, consequently, the rate of mortality deduced therefrom is also erroneous.

From the deaths which have taken place in "All Saints" parish, Northampton, during the seven years, 1838-44, being the same district to which Dr. Price's facts relate, Dr. Farr has constructed a Table of Mortality, on the plan adopted by Dr. Price in the construction of his Table for the forty-six years, 1735-80, and, although an interval of sixty years has elapsed between the periods to which each class of facts belong, still it is curious to find that little or no change has taken place in the rate of mortality, and the one Table might be used for the other.

It is however important to understand that the method followed by Dr. Price in the construction of his Table is now admitted by all authorities to be wrong, and any one who, at this time, would venture upon a similar course must necessarily sacrifice all public esteem for scientific accuracy.

The parallel Table by Dr. Farr has been purposely constructed on the same plan, and the results of both agree so closely that it is impossible for any one to argue therefrom, that since the middle of last century any improvement whatever has taken place in the duration of life in Northampton.

Dr. Farr has, however, not stopped at this stage of the inquiry, but has gone further. He has formed a Table on true principles from the data referred to, for the seven years 1838-44, and the results arrived at do not differ widely from the rate of mortality shewn in Mr. Milne's Carlisle Table and other Tables still more recently promulgated.

If, therefore, the facts treated by Dr. Farr on true principles shew so great an improvement in life, there is every reason to believe that the materials with which Dr. Price had to deal would also have shewn similar results had they been properly treated, and consequently, so far as the Northampton and Carlisle Tables are concerned, there is no reason to believe that any augmentation has taken place in the duration of life during the last hundred years.

The Northampton and Carlisle Tables have been dwelt on from the importance they have assumed in the practice of life offices.

There are, however, other local Tables, as the Chester and others, to which reference might be made if necessary. Proofs of the like stability in the rate of mortality may also be derived from observations of large masses of mankind.

The mortuary registers of Sweden, in a very complete form, go as far back as the

year 1751, and up to the present time no improvement appears to have taken place in the duration of life. The result for that kingdom for the last hundred years do not appear to differ much from the rate of mortality in this country during the last fifteen years.

Again, in France, if the Tables of Demonferrond are to be relied on, the value of life there does not differ in any material degree from that indicated by either of the other classes of results.

It is, however, right to remark that the French people, although so much advanced in scientific knowledge and civilisation, are still indifferent to the advantages of a proper census of the people, and M. Demonferrond has been compelled, owing to the ages of the population being unknown, to resort to an expedient in the construction of his Table which, although generally unsafe, may in his particular instance probably not affect the value of the results in any serious degree.

Life offices in this country have had their transactions almost exclusively with the middle and upper classes, and the same remark is to a great extent applicable to the experience of companies on the Continent and in America; therefore whatever value may be attached to any of the mortality Tables hitherto referred to, they cannot, in the absence of other evidence, be considered as strictly applicable to the purposes of assurance companies.

The public is indebted to the elder Mr. Finlaison for what is called the Government Tables; but these, irrespective of inherent evidence of anomalous conditions, could scarcely be thought applicable to the purposes of a life office: for as the bulk of the data has reference to a remote period of years, if any value is to be attached to prevailing opinions on the recent improvement of life, the data must be wholly inapplicable to the present time.

It may also be here remarked that, as pointed out in page 42 *seq.*, that those usually quoted as the Government Tables are not those based on the corrected and revised data of 1829; but the Tables given in the Reports of 1824, and that which the public really speak of as being the Government Table, is not in fact the one finally adopted. We have, however, Tables derived directly from the experience of life offices,—the Equitable and Amicable Societies,—but the bulk of the facts of both Tables relates to remote years, and therefore if any importance is to be attached to the recent improvement in life they are clearly not applicable to the present operations of assurance companies.

There is likewise the Table usually denominated the "Experience Table," deduced from the recorded observations of fifteen life offices, in addition to those of the Equitable and Amicable Societies already mentioned, reported on by the committee of actuaries appointed in the year 1839. In these observations, like those deduced from the Amicable and Equitable Life Offices, the principal portion of the data has no reference to recent years; but there is a much more serious objection to be brought against the results given

in the "Experience Table." From the indisposition evinced by the contributing offices to let their individual experience be known, even to the members of the committee to whom the inquiry was entrusted, it became necessary that the different schedules should be submitted in an anonymous form: all were given with blank headings, and so completely mixed up together that it was impossible afterwards to determine from what office any particular schedule came.

This arrangement prevented the investigation being any other than one confined to policies issued by those offices, and not an estimate of the mortality among a certain number of lives.

To those, therefore, of even limited experience, it must be obvious that the results are thereby deprived of all value as indicating the rate of mortality among the offices contributing the facts.

Nothing is more notorious than the frequency with which the same life is assured in duplicate and triplicate, not only in the same office but in several offices, and it often happens that on the same life there has at one time or another been issued, as many as from twenty to fifty policies in the different offices conjointly. To take an extreme example, in order to shew the nature of the principle and its effect in vitiating the truth of any results derived from a calculation founded on the number of policies, and not upon the number of lives.

It is well known, in most of the assurance offices, that a distinguished personage was so fully assured in the life offices in this kingdom that it was impossible to obtain any further policies on his life from assurance companies, and it has been said that recourse was had to Lloyds to have the life underwritten there. The policies existing upon this life, at one time, it has been considered could not be less than three or four hundred. It is hence evident that a death taking place under such circumstances would, in the result of such inquiry, appear as three or four hundred deaths, while in fact only one had happened.

In like manner, the fact of the life still surviving would produce the anomalous result of there being 1000 or 2000 years of risk depending upon the duration of these policies without any recorded death.

It is therefore clear, that unless the principle of repeated policies on the same life was uniform as to numbers, and very generally characteristic of all the assurances effected, that compensation errors could not be expected to take place sufficient to render the results even a near approximation to the truth.

So far, therefore, we are yet without any satisfactory data, derived directly from the life offices of this country, which can be relied on as indicating the rate of mortality among the assured classes in recent years.

On the Continent, however, we have been furnished with the experience of the

Gotha Life Office, and in this instance the results are free from the objections just alluded to, as the investigation has been conducted on the number of lives, and not on the number of policies. The experience of the Gotha Life Office, as given in pp. 151–200, shews a remarkable and peculiar feature in the state of mortality to which the members are subject. At the younger ages, the mortality is much less than that indicated by any of the other Tables yet alluded to; but at the older ages the rate of mortality is very much greater.

At present it is difficult, if not impossible, to account for this peculiarity, whether it be due to the different circumstances and habits of life of our continental neighbours, or whether it arises from some mutation in the physical condition of the assuring classes in recent years, and is common to our own country, it is difficult to say, for we have no sufficient amount of data relating to the last twenty-five years, within which the facts of the Gotha Life Office are limited; but that some such explanation may be possible is supported by the large body of facts analysed in the following paper, on the Mortality of the Provident Classes in this Country and on the Continent.

Professor Gill, the late Actuary of the Mutual Life Assurance Company of New York, has reported on the rate of mortality among the members of that society, during the eight years which had elapsed between its establishment and February 1851, and although the experience is not so extensive as that of the Gotha Life Office, still it embraces between 17000 and 18000 years of life, and is therefore valuable and curious, as shewing the same peculiar features in the rate of mortality described as characteristic of the Gotha Company's experience, only at the older ages the mortality is even higher than that of the other.

It would certainly be of great importance to the interests of life offices to determine accurately whether this be a permanent feature of the mortality prevailing generally, not only in this country, but elsewhere, among the assuring classes; and it is to be hoped that an effort will be made at no distant date to collect and convey, in an intelligible and satisfactory manner, the experience of the different assurance companies.

It should not, however, be lost sight of, that the rapid extension of the practice of life assurance of late years will render the data derived from the past experience of life offices yearly less applicable to their future operations.

Hitherto Life Assurance has, to a great extent, been confined to the comparatively wealthy, but now the practice seems to extend to the less wealthy and the humbler classes, and is, in fact, almost universally recognised by the industrious workmen of the country in connection with Friendly and Benefit Societies.

It may be stated that there is little chance of a future generation of the gigantic corporations boasting of their millions of invested capital and revenues, exceeding those of some of the States of Europe, springing up. It is more likely that an intermediate class

of companies will be called into existence, holding a position between that of the great corporate bodies established in the last and early in the present century, and the humble Friendly Society with which the working classes are familiar. If this supposition be well founded, or if it be admitted that Life Assurance will rapidly extend itself among all classes of the people, it is evident that the rate of mortality among the assuring classes must gradually approximate to that of the country generally.

No principle in vital statistics is better established than the widely-differing rates of mortality among different classes and ranks of society, and the more that assurances are confined to individual classes the more peculiar ought we to expect the rate of mortality to be, but, as the practice of assuring ramifies itself among all classes, so also will the rate of mortality gradually assimilate to that of the country at large; there is consequently reason to conclude that, with the extension of Life Assurance, the rate of mortality will become more favourable.

In support of this statement there is the most abundant evidence.

The past experience of Life Offices, as far as it can be made available in the solution of such a question, shews that the rate of mortality among the assuring classes, which chiefly belong to the middle and upper walks of life, is greater than that of the population at large. See Table H, No. 5, and pp. 39-42.

The corrected experience of the Government male annuitants also shews a higher rate of mortality, and, taking the result of observations on the Peerage as given by Mr. Edmonds and Dr. Guy, the rate of mortality among the highest ranks of society is very much greater than that of the whole population of this country. It will likewise, I have no doubt, be admitted that among the intemperate, the destitute, and the dissolute, the rate of mortality must also exceed the average for the people at large; hence, since all these groups experience a rate of mortality above the average of the whole population, there must be somewhere among the people a class which is subject to less than the average mortality; that class it is evident, from the exhaustive enumeration of the above groups, must be the industrious, provident workmen of our country, who do not fall within any of the other sections of the people just spoken of.

But the following pages contain much direct evidence to shew that the prudential portion of the working classes are really subject to a less rate of mortality.

Early in this century, considerable attention was given to the nature of Friendly Societies or Sickness Clubs, and, since the year 1824, the question of the sickness and mortality to which the members are subject has also engaged public attention, while, since 1835, some evidence of the rate of mortality prevailing among those societies has been before the country, and, for the last ten or eleven years, it is submitted that the present contributions has afforded the most conclusive evidence that the duration of life among the members of Friendly Societies generally is much greater than that of the country at

large, or the select classes dealing with Assurance Companies. Mr. Ratcliffe's investigations into the experience of Odd Fellow Societies, and the more recent inquiry made on behalf of the Government, and described in pp. 440-6, fully support this view of the question.

This immunity from disease among the humble and industrious workmen of the country, whose prudential habits are sufficiently strong to maintain them members of these clubs, is only what *à priori* might be expected. The fact of continuing a member of such a society pre-supposes great regularity of habits, otherwise difficult circumstance and distress would ensue, and, from inability to continue his subscription, non-membership follow. Hence, such a member may be regarded as a type of industry, frugality, regularity of habits, and simplicity of life.

If the health of the body is to be maintained it must co-exist with regularity of habits and uniform physical exercise. The member's avocation enjoin on him a diurnal repetition of the different functions of the body in a manner not required of the pampered, the indolent, the intemperate, and the dissolute. He has, therefore, his legitimate reward in the enjoyment of a long, a useful, and let us hope a happy and blessed life. If the operations of Life Assurance Companies should ever extend so as to embrace the classes now comprising the Friendly Societies, it is evident that the rate of mortality must diminish rather than increase; but should the practice of assuring lives stop short of that, it is still obvious that the same principle will hold good, although the improvement in health may not increase to the same degree.

Having dwelt at so much length on the nature and extent of the data now chiefly in use for the purpose of Life Assurance, it may not be out of place to point to an immense field in Vital Statistics which still remains uncultivated.

One of the most obvious which yet remains untouched, so far as the middle and wealthier classes are concerned, is the mortality of children. Private monographs I know exist on this question, but they are not yet available for public use; the following questions are of great importance to the actuary, not only in the more ordinary exercise of his functions but also in the special cases on which his advice is frequently sought by the public.

The influence of age at marriage on the fruitfulness of the marriage.

The influence of age at marriage on the mortality of children born therefrom.

The influence of age at marriage on the sex of issue, and also on the relative mortality of the first, second, and third born, as well as on each subsequent birth in consecutive order.

The probability of marriage in different ranks of life for each age and sex is also important to be determined; but one of the questions in which the actuary should be most interested, and for which he is but indifferently prepared at present, is that of the tests which should be applied to members seeking admission into an Assurance Society.

The very mention of this subject opens up to view a most fertile field of inquiry, almost entirely neglected even by the Medical Profession itself. Among more obvious questions may be mentioned the power of diseases usually called hereditary in developing themselves in succeeding generations of families in which they have once appeared.

The relation of mortality in general in one generation to that of the next generation.

Relation of the mortality in one section of a family to that of another or surviving section of a family.

The probability of the development of infantile and other non-recurrent diseases in relation to age.

The influence of infantile diseases on the mortality of survivors to mature life.

The practical importance of the preceding questions must be evident to those of even the most limited experience.

At present nothing but arbitrary tests exist, and, consequently, all the absurdities of caprice, instability, and prejudice, interpose in the place which should be occupied by the science, judgment, and disciplined skill of the actuary.

To obtain this amount of new data will involve great expense, much labour and patience, still abundant materials exist to afford the information required, and all that is needed is a resolute attempt to conquer the difficulties, but it is too much to expect that private individuals can afford to go to the expense of collecting materials for the purpose of enriching public companies, already plethoric in wealth, and whose speculations have been notoriously profitable in the history of trading enterprise. On this subject see the concluding paragraph in page 144.

The proper parties to bear the expense are the companies themselves. A few thousands out of the millions possessed by the assurance companies devoted to the acquisition of accurate data on the subject discussed would form one of the wisest and best investments which they could devise, and place their actuaries in the proper position of having to deal with facts and established principles, instead of the dogmas of prejudice and ignorance.

It may on first view occasion some surprise to find a Paper on Criminal Statistics in a work purporting to be Contributions to Vital Statistics, but I have no doubt a careful perusal of pp. 302-407 will satisfy any inquirer that every proper investigation into the state of crime of a country involves the consideration of so many of the most important elements of its vital statistics that the one branch of study necessarily includes the other. On examination of the large body of facts contained in this Paper, and the mode in which they have been treated, it will be found that the minuteness of detail into which it has been necessary to enter for the proper determination of the duration of life in various classes in the community, is even still more necessary for solving the different questions brought under discussion in regard to the prevalence of crime; in fact, until proper adjustments and corrections have been made on account of differences in the distribution

of the population according to age in different districts and communities, there is no possibility of arriving at correct views as to the relative tendency to crime in different districts of the country. As the population of every district is constantly undergoing changes in these conditions, such corrections are equally necessary, in order to determine whether crime be increasing or decreasing within given periods, either in the whole kingdom or in particular parts of it. An examination of the facts given in pp. 302-25, and in Table VII, page 322, shews, that if the tendency to crime had remained constant the distribution of the population of England and Wales, as in 1820, would give a ratio of *one* person in 365 of the whole male population being committed for crime in the course of the year; but, in 1841, the ratio would be *one* in 339; but by the census of 1851, the ratio would be also *one* in 339. Again, it will be found that between different districts of the country no correct comparison can be made unless such corrections be in the first place carried out. Otherwise it would appear that, on the assumption of the same tendency to crime existing there would, owing to differences in the distribution of the population, in one district of the metropolis, Bethnal Green, for example, be the ratio of *one* committed in 338 of the population, and in St. George's, Hanover Square, *one* in 280. Again, in Anglesea, Cardigan, Carmarthen, Dorset, Merioneth, Montgomery, and Pembroke, the ratio is *one* in every 360 of the male population; while in Glamorgan, Lancaster, Middlesex, and Monmouth, the same tendency would produce as high an average as from *one* in 325 to *one* in 315. This question is fully discussed throughout the Paper, and some striking examples given of the facilities afforded by attention to this element of the investigation while interrogating other features in the development of crime. The necessity for this correction arises from the fact that the tendency to crime at one period of active life is in both sexes more than quadruple that at another term of life, and also that the ratio of crime in the male sex is nearly five times as great as in the female sex, and, consequently, different ratios of the two sexes, and also differences in the distribution of the numbers of either sex, according to age, in different localities will produce apparent differences in the ratio of crime, when viewed, as is usual, in regard to the aggregate of the population only, although the actual tendency to crime at corresponding ages in the respective sexes may be precisely the same.

On referring to pp. 325-6, a curious law is disclosed as regulating the development of the aggregate crime at various ages. This law, if attentively considered, is calculated to throw much light on the progress of crime; but an examination of the analysis made of the tendency to specific forms of crime, in pp. 391-8, will shew how remarkably different is the law which regulates the tendency to particular forms of crime at different ages, and how unsuccessful all preventive measures must be unless an accurate knowledge exists of the particular tendencies to certain propensities and forms of crime at the different terms of life.

During the last quarter of a century much has been said and written, particularly in this country, and in France, on the statistical evidence which affects the relation between education and crime, and the very opposite conclusions arrived at by different inquirers it is submitted are quite reconciled by the more complete and accurate mode of investigation explained and followed out in pp. 353-91. If the crime which has hitherto prevailed in the various districts and groups of counties be analysed in the manner pointed out, so that the groups compared differ in respect of education only, it will be found that out of twenty-two different combinations formed of all the different districts of England and Wales, that in every instance there is an excess of crime where there is the least education or instruction, and comparing the respective sections of each group of counties, it will be found that there is an average excess of 25 per cent. of crime in the sections of inferior education over those of higher education, while in some districts the excess is as much as 44 per cent. These results, it will be seen, are derived from the application of the educational test to the general population of the district in which the crime is investigated; but the same contribution also shews that invariably in those districts in which there is an increased amount of crime there is likewise a higher ratio of uneducated criminals, and in the less criminal districts a smaller proportion of the criminal population is found to be wholly destitute of the rudest elements of education, and, continuing to trace the details of this investigation, there is found the following very remarkable combination of elements in the manifestation of crime.

The districts of the country in which the general population is the worst educated, the districts in which the greatest amount of crime prevails, and the districts in which there is the highest proportion of uninstructed criminals, are constantly found assimilating; while, on the other hand, those districts which are the best educated, the least criminal, and in which shews a smaller proportion of uneducated criminals, are likewise found to be identified in the various combinations.

It is hence obvious that the very small amount of education, or rather instruction, implied by the test employed in the following investigation, must have a powerful influence on the criminal calendar of the country, and a great reduction of crime may be therefore justly expected from a more general diffusion of education.

It may not be altogether out of place to remark here, that if the term education be held to signify the culture and elevation of the moral character, it is evident that its immediate and essential influence would be to destroy crime; in fact, in this sense, education and freedom from crime must bear the relation of cause and effect; and therefore, when education is at a maximum crime must, of necessity, be at a minimum; so that, if the term be thus explained, statistical evidence would be *à priori* unnecessary to solve the problem proposed: but if the term education be used in its ordinary acceptation, merely to imply instruction, it then becomes a fit and proper question,

whether education in this restricted sense has any influence on the repression of crime.

The educational tests employed in the following Contribution are fully explained in pp. 353 and 377, and it is believed that a careful perusal of the whole of the Paper on the Statistics of Crime, and the methods of investigation followed will, in the results arrived at, surprise even the best informed readers in finding so low a test of education or instruction as that employed to lead to so striking differences in the criminal condition of various districts of the kingdom. These results are, in every instance, so constant and positive as fully to establish the conclusion that education is one of the most powerful preventives of crime. Whatever other combinations may be attempted or made in the analysis, of which a great number will be found in connection with the manufacturing and agricultural condition of the various counties, no solution is arrived at as to what is the element or feature which produces in one great community an excess of fifty-two per cent. of crime, and in another reduces crime thirty-three per cent. below the average, but introduce the educational test and the whole problem is completely solved.

Immense correctional efforts are at the present time made in the shape of reformatories, and other institutions for the treatment of convicted criminals, but little or nothing is done to remove the causes of crime; and if it be admitted, as it is presumed from the evidence adduced in the following contribution, that education is the most powerful agent yet known in counteracting the criminal tendencies of the population, it becomes a question of vital importance for the Legislature to decide whether some more complete system of education, which would reach and saturate the whole juvenile population, should not be speedily devised. The country exercises the right of punishing crime, and it is a fair question for consideration whether it should not also recognise the duty and responsibility of removing some of the causes of crime. In the following paper it will be found that to one class of offences—those against property, committed without violence—are due three-fourths of the whole crime of this country; and, among the population of sixteen years of age and under, more than nine-tenths of all their crimes belong to this single class of offences. A few minutes reflection is enough to shew how soon a general and amply-developed system of education would tell on that portion of the rising population, who without it must soon swell the criminal calendar of the country.

The Contribution on the Statistics of Crime in England and Wales contains many other curious and important points of inquiry, and gives an analytical view of the Criminal Returns of this country for the twenty years 1836–55; and in pp. 403–7 will be found a condensed recapitulation of the general results of the investigation.

An examination of the course of inquiry pursued will lead every one seriously interested in the moral condition of the country to view with pain and regret the present most defective character of the Home Office Returns; in fact, for all statistical purposes

they are now worse than useless. They cannot, it will be found for reasons hereafter advanced, be employed in any exact inquiry. Ever since the year 1839 these Returns have been periodically undergoing such changes, and have been from time to time presented to the public in so defective a shape, that in the hands of unskilful persons they are likely to lead to the most erroneous and fatal conclusions.

At a time when throughout the whole civilised world the most strenuous efforts are being made, not only by individuals but by Governments, to systematise the records of all facts and phenomena bearing on the social and moral progress and happiness of the people, it is lamentable to find our own Home Office Returns in so retrogressive a condition as that pointed out in the commentaries in pp. 398-400.

It is believed that the elaborate analysis of Railway Accidents, given in pp. 230-301, for the period commencing the 1st of January, 1840, and ending 31st of December, 1856, if carefully studied by those entrusted with the details of railway management, would soon lead to many improvements which would speedily effect a great reduction in the number and severity of the accidents.

This Contribution cannot however fail to shew how erroneous the general impression on the public mind is in regard to the dangers of railway travelling, and more particularly so as regards the indiscriminate blame to be attached to the system of railway management.

The Paper contains evidence not only of a great diminution of all kinds of accidents, but, what is exceedingly satisfactory, of those accidents which are due to causes assumed to be under the control of the Companies. It is shewn, that while deaths from causes beyond control of the Companies have in the more recent years diminished in the ratio of 49 to 30, those from causes under control of the Companies have diminished in the ratio of 64 to 19. This result is certainly one not generally understood by the public, for not only are all railway accidents supposed to be very much on the increase, but those due to details of management are believed to be rapidly and alarmingly so. The facts of the case, however, do not support this view, for they disclose the truth that railway management, so far as accidents producing death are concerned, has greatly improved. Whether this change be due to the better general regulations enforced by the Directors of the Companies, or to the improved skill and intelligence of their officers and servants, still the results of the investigation afford the most striking testimony to the recent improvement and increased safety in railway travelling, and encourage the hope that the same means will be persevered in to effect a still further reduction in the frequency and intensity of railway accidents.

It has been said that the great bulk of accidents is due to collisions, but an inspection of Table XXI, page 257, will shew that they constitute the causes of 22·5 per cent. only of the whole deaths amongst passengers, and if the deaths of employés be included,

not quite one-fifteenth part of all the deaths are occasioned by collisions. An examination of the figures in Abstract L, page 261, will shew that the deaths of passengers from collisions at stations have in recent years decreased to about 58 per cent. of their ratio in earlier periods, and those from collisions elsewhere than at stations have been reduced to 25 per cent. of their original amount.

It is, however, most lamentable to learn, that of 174 collisions of which the causes are classified in Table XXII, page 263, no less than 104 have arisen out of what can be described as nothing short of the most culpable neglect. The facts recorded in that Table are of great importance, and although the Directors of Railway Companies have in recent years done an immense deal to protect passengers against loss of life and limb, they are still imperatively called on to take the subject of the frequently recurring collisions more thoroughly into consideration. When such most culpable neglect exists, as is evident by the facts disclosed in pp. 263-4, the public have a right to demand more complete protection. Much interesting information will be found in pp. 261-73 in regard to collisions and the manner in which passengers are affected by them.

The other important kinds of accidents from which passengers suffer, and which are assumed to be under the control or management of the Companies are those occasioned by trains or portions of trains running off the line. It will be found that they occasion 32.1 per cent. of all the deaths of passengers from defined causes. In fact, "collisions" and "running off the line" have caused 91 per cent. of all the deaths of passengers for which the Companies can be supposed responsible.

On referring to Table XXIX, page 276, a strange circumstance is observable. From the 51 cases of trains, or parts of trains, or engines "running off the line," occasioned by the state of the weather or machinery breaking, not a single death of a passenger happened, while the 30 cases of "running off the line," owing to the defects in the permanent way, produced eight deaths of passengers.

In regard to the collisions which have taken place from defects and breakage of machinery, the case is however unfortunately very different, for 34 collisions, attributable to this cause, occasioned as many as eleven deaths of passengers, and no less than 208 serious injuries. The causes of these are certainly, to a very great extent, completely under the control of the Companies. Of these 34 collisions, the great bulk was absolutely preventable by a sufficient amount of care. For example, an examination of Table XXII will shew that no less than fifteen are due to portions of the train becoming detached, and three to defective "breaks," and it is difficult to conceive any sufficient reason to justify a continuance or repetition of accidents from these causes. No doubt the coupling of carriages may, under extraordinary circumstances, be found to give way, even when great vigilance has been used; but such an excuse can be of no avail in the face of so many accidents of this kind, and there certainly does appear strong reason to

condemn the system of management which permits a series of collisions from such causes. In the same Table it will likewise be found that sixteen collisions actually took place owing to trains having been retarded by accidents to some portion or other of the engine. It is no doubt sometimes difficult to determine on inspection the defects in the mechanism of an engine, still the collisions from this cause have been so many that it is impossible to conceive that a due amount of scrutiny has been always exercised in the examination of the state of the locomotives. Defects and breakage of machinery have caused, either by "collisions" or "running off the line," as many as seventy-seven accidents, which have resulted in thirty-seven deaths to passengers and employés, and the large number of 273 serious injuries. Frequent inspection by competent parties is the protection against this group of accidents, and strong measures should be enforced to secure the safety arising from proper supervision.

Of the 308 collisions recorded in Table XXVII, page 272, no less than 110 have taken place at stations, or the very places where the greatest care and vigilance are required, and might be exercised. Anything like fair attention to the use of well understood precautions, and a proper employment of signals and telegraphs, should completely, or at all events to a great extent, remove this class of accidents.

The latter portion of the Contribution on Railway Accidents, pp. 278-301, merits deep and serious consideration owing to the results exhibited of the frightful amount of accidents and fearful loss of life to which the servants of Railway Companies are exposed. The facts contained in that portion of the Paper are of a very curious and certainly of a very striking nature, and must enlist, on behalf of the more important class of railway employés, the sympathies of all who may give those pages a careful consideration.

In pp. 93-9 are given several important facts relating to the Registration Act for Scotland, the 17th and 18th Vic., cap. 80, and illustrations furnished of the schedules and certificates proposed for use under that Act. During the year 1855, the first year in which the provisions of the Act were in operation, the complete schedules as contained in the Act were employed by the various Registrars, but since the beginning of 1856, those forms have been thrown aside, and schedules substituted which are scarcely more complete than the very meagre and defective forms now employed under the English Registration Act. This change is very much to be regretted, for any thing short of the original requirements of the Act cannot possibly supply the information so much needed for the legal purposes of the country, and demanded by the present state of statistical science.

The reasons assigned for making the change is the difficulty said to exist in procuring from all parties the full amount of information required by the Act, but it is very much to be feared that on this ground there is not sufficient justification for the alteration which has

been made. In page 99 *seq.* the probability of this difficulty arising was anticipated, and it was suggested that in Scotland, where no National Registration previously existed, the people would need, during the first few years of the operation of the Act, to be instructed as to the precise kind of information to be furnished in the event of a birth, death, or marriage. Had this been properly attempted and persevered in for three or four years no more difficulty could have been experienced in carrying out the original complete system of Registration than the present very defective one which has been substituted for it. Some influential member of the Government, it is hoped, will speedily take steps to cause the forms prescribed under the Act to be resumed, and their use may, in that event, before long be extended to England.

The Contributions on the Rate of Mortality in the Medical Profession, the Mortality of Master Mariners, and the Mortality among Persons of Intemperate Habits, contain many interesting results not appearing in any other Papers on Vital Statistics. In the latter of these there is a somewhat unexpected coincidence pointed out in page 225, in the remarkable similarity between the proportion of crime in the sexes to the proportion of deaths from assigned causes of intemperance. This question is worth further investigation, but not falling strictly within the scope of the present Contributions the inquiry has not been entered upon at much length.

Those interested in the management of Friendly, Benefit, and other kindred Provident Societies will find a large amount of information in regard to them in the following contributions.

The laws of sickness and mortality, as observed in the experience of these societies, are fully discussed in pp. 17-82, 160-4, and 408-68, and a great variety of data furnished, shewing the influence of trades, occupations, and local peculiarities on health. In the thirteenth edition of "Odd Fellow and Friendly Societies," published in the year 1851, it was stated that one of the most important questions which appeared to have engaged the attention of the recent Parliamentary Committees on Friendly Societies, was the sufficiency, for the purposes of Odd Fellow Lodges, of the data brought before the public in the first and second editions of this work—several of the witnesses examined contending that these lodges were exempt from much of the sickness to which Friendly Societies in general were subject: however, all doubts on this question have been removed by the publication of the rate of sickness actually experienced by the "Manchester Unity," and the results, it will be found from the analysis of them, given in pp. 423-8, *seq.*, confirm in a most remarkable manner the law of sickness developed in these Contributions. A striking practical illustration of this fact will be found by comparing the financial results of both sections of Table AX, page 496, deduced from the actual experience of the Order, with the corresponding results in Tables AR and AS,

pp. 479–80, which are based on the data originally appearing in these Contributions. The very remarkable agreement of these two classes of results, considering the data to have been collected from very different sources and by means quite independent of each other, must be exceedingly satisfactory to those interested in the progress of these institutions. It is understood to be the intention of the Manchester Unity, to make a further inquiry into the nature and amount of the sickness which prevails in the Order, and with this view the various lodges will be required to make the necessary returns of their experience, at the expiration of the next quinquennium, the end of the year 1860, and until then nothing further will be known of the ratio of sickness to which the great body of the Odd Fellows is subject. The analysis of the facts, already referred to, however, pretty conclusively shews, that whatever may be the experience of individual lodges they have, taking them in the aggregate, no immunity from the sickness hitherto indicated as characteristic of Benefit Societies in general, and a perusal of the various Quarterly and Annual Reports of the Unity, distinctly shews this to be now the opinion of most of the best informed members of the Order.

Attention is particularly directed to the observations and facts in pp. 440–6, on the Government Analysis of the sickness experienced by Friendly Societies during the quinquennium 1846–50, and printed in Parliamentary Papers No. 955 of 1853, and No. 506 of the year 1854. Since the disastrous publication of the Highland Society's Tables in 1824 perhaps no other so unfortunate event as the publication of what is termed the Government Tables has arisen in the history of Benefit and Friendly Societies, and into the nature of the mischief likely to be occasioned by it, I have fully entered in the pages already referred to. A careful perusal of those observations must satisfy every one, having a practical knowledge of the management of Friendly Societies, of the imminent danger of circulating such documents under Government sanction. If those entrusted with the Analysis of the Government Sickness Returns had but asked themselves the simple question—What is the true object of a Friendly Society? it is impossible they could have excluded from their analysis “chronic ailment,” “mere decrepitude,” “slight paralysis,” “blindness,” “mental disorder,” and “senile infirmity,” and have only included in the published results, presented for the guidance of Friendly Societies in the country, “sickness incapacitating from labour, *requiring constant medical treatment*, and of *limited duration*.” The object which a working man has in view, in joining a Benefit Society, is not only to provide for sickness of *limited duration, requiring constant medical treatment*. If this were the only purpose of Friendly Societies, they would be nothing more than a delusion and a curse to a provident working man. Against sickness of *limited duration*, men, whose prudential habits are sufficiently strong to retain their membership in Friendly Societies for two or three years, can, with a struggle, make provision even without the aid of a society; but how many working men can contend against the vicissitudes of any

description of "*chronic malady*," or protracted sickness? The true object and mission of Friendly Societies, when properly considered and as regarded by the working man himself, is to afford him a competent support and complete independence during periods of sickness, incapacity, and disease, however protracted; and it is to accomplish this object that not only the earliest but the most recently and best organized societies make special provision. Their object is not to form a stepping stone, to aid the industrious and prudent to pass from the active and manly independence of their days of vigorous labour, to the degraded pauperism of the Workhouse. Were Friendly Societies so constituted, they would be a disgrace to the country, and could never receive the support and sympathy of the people.

This is however the only practical effect which the general dissemination of the two Parliamentary Papers referred to can have, for by causing Friendly Societies to adopt scales of contributions and benefits, which make no provision for those very vicissitudes which are in fact the most trying to a member's independence, he is, at a time when the least prepared for it, declared off the funds of the Society, and has of course no alternative but to take shelter under the roof of the Workhouse. That this is the real direction and tendency of these Parliamentary Papers is fully shewn, in the Appendix to the First Report of the Registrar of Friendly Societies in England and Wales, dated the 18th July, 1856, and ordered by the House of Commons to be printed 21st July, 1856. The portion of the Appendix in question commences in page 37, and is entitled "Suggestions by John Tidd Pratt, Esq., the Registrar of Friendly Societies in England, for the establishment of Friendly Societies; with Tables of Contributions for payments in sickness, &c."

In page 39, he states that "Provision should be made, in the Rules, that nothing but sickness incapacitating from labour, and requiring constant medical treatment, and of limited duration, as contradistinguished from chronic ailments and mere decrepitude,—should be provided for, and that slight paralysis, blindness, mental disorder, or senile infirmity should not entitle a member to sick-relief from his society." And again, at page 48, it is stated that the Tables "are not intended to meet the case of chronic infirmity demanding little or no medical attention."

This is certainly a most extraordinary suggestion to come from one holding an appointment of so high pretensions. It would be interesting to know the Registrar's views of what the establishment of a Friendly Society is meant by him to effect. It surely cannot be his object to work out a mere problem in medical science, in order to determine the relation between acute and chronic diseases; and still looking at his suggestions in the most favourable light it is possible to regard them, no one can conclude that there is any intention to make Benefit Societies self-supporting Provident Institutions, which shall, during the physical vicissitudes to which all flesh is heir to, render their members

independent of the Parish and the Workhouse. A distinct provision is suggested to be made in the Rules to prevent members from receiving any relief during "chronic infirmity demanding little or no medical attention." Admitting, therefore, that it is quite possible for the members of a society to discriminate between cases of "chronic ailment and infirmity," in a way to effectually prevent litigation with sickness claimants, let us see what would be, under such circumstances, the position of the members of a society formed on the model recommended by the Registrar. On referring to pp. 445-9, *seq.*, a considerable amount of data will be found, shewing the ratio of protracted sickness to sickness generally: after the age of 40, it will be seen from Table NN, page 446, that the ratio of the number of persons suffering from protracted sickness to the total number of persons actually sick increases very rapidly, and during the term of life 41-70, the average ratio is as high as 14·5 per cent., the shortest duration of any one attack of such protracted sickness being one year, while many of them are of course of several years' duration. In the decennium of life, ages 61-70, the cases of protracted sickness extend to nearly 48 per cent. of the whole number. In the Appendix to Mr. Ratcliffe's Report, already referred to, and published with the Quarterly Report of the G.M. and Board of Directors, for January 1853, will be found some valuable information on this question; but the form in which the results are presented by Mr. Ratcliffe, does not shew the number of members subject to protracted sickness, but simply the average amount of that sickness to all the members of the lodges over which the observations extend.

| Ages. | AVERAGE SICKNESS PER MEMBER EXPERIENCED |                                     |                                    |                                                                      |                        |                        |                              | Ages. |

| 68    | 3·1666                                  | 1·3142                              | 2·4712                             | 6·9265                                                               | 18·9735                | 35·6775                | 54·6510                      | 68    |

It will thus be seen, that the average amount of sickness, in column (3) of this abstract, experienced within the second twelve months of sickness, ranges from 2·8952

per cent. to 19·8092 per cent. of the total sickness to which the members are liable; and the average amount of sickness, in column (4) experienced after the second twelve months' illness, varies from 2·2708 per cent. to 35·6775 per cent. of the total sickness; the ratio of protracted sickness to the whole amount of sickness, in both columns, increasing with advance of age, as shewn in columns (6) and (7). If attention be now given to the results of column (8) of the preceding abstract, they will be found to throw considerable light on the painful condition in which those societies which, following the advice of the Registrar, adopt the Government Tables, must be placed. It will be there seen, that the protracted sickness varies from 5·1660 per cent., of the total sickness, at age twenty-three, to 54·6510 per cent., at age sixty-eight. These results, with those already quoted from Table NN, page 446, shew abundantly the serious defects in the Government Analysis. But it may be still important to refer to Table QQ, page 448, in which will be found some curious information on the relation of permanent to temporary sickness under various forms of disease, and it will be found that in Class IV, Diseases of the Brain and Nervous System, there is the highest ratio of permanent and protracted sickness; and viewing that fact in connection with the results in Table XIV, page 182, and the Abstract in page 183, it will be seen that after the age of 40, this class of diseases grows rapidly in intensity, and hence the frequency with which, after that time of life, members of Friendly Societies will become claimants for permanent and protracted sickness.

The question now arises, what are the members belonging to those societies, formed in accordance with the advice of the Registrar of Friendly Societies, to do while suffering from this protracted or "chronic" sickness? They can get no relief from the society, and in his Report and in its Appendix of Suggestions, not a single syllable is written on the subject, in fact all allusion to this important feature is carefully avoided; and from pp. 444-5, *seq.*, it will also be found that in the published Analysis of the Government Returns themselves, the nature and extent of the "chronic ailment and mere decrepitude" are nowhere given, so that so far as those documents and the Registrar's instructions are concerned, the promoters, and those interested in the management of Friendly Societies, have no choice, but to follow implicitly the Government Tables, and permit about one member in seven, of the sickness claimants, above the age of forty, to be drafted to the Workhouse. Had the eliminated elements, in question, been given as a separate and distinct series of results, data would have been available for societies to make the necessary provision for "chronic ailment and mere decrepitude;" but nothing of the kind has been done. It is therefore hoped, that all interested in Friendly Societies will soon become fully aware of the defective and most disastrous aspect under which the results of the Government Analysis of Sickness has been submitted to the public.

I have elsewhere shewn, that any one giving attention to the examination of the different witnesses, before the recent Parliamentary Committees, must have observed a

strong tendency, on the part of the members, towards the adoption of Model Tables of Rates of Contributions and Benefits. In Appendix (A) to the Report by the late Lord Beaumont's Committee, House of Lords, Session 1847-8, paper No. 126, I have furnished some striking illustrations of the varying liabilities to which different societies are subject; but the additional examples, now furnished in pp. 408-530, are certainly very curious and remarkable, both in a scientific and practical point of view, and conclusively prove that few things could be more dangerous to the interests of Friendly Societies, than the adoption of Model Tables. There is nothing connected with the study of a statist and the profession of an actuary, requiring more judgment and experience, than the proper discharge of the duties devolving on him in giving advice to Benefit Societies, and every day shews more clearly, that the circumstances in which different societies are placed, are so dissimilar as to render the liabilities of one, no criterion for those of another.

The members of Benefit Clubs and Odd Fellows' Lodges, should give serious consideration to pp. 513-21, *seq.*, on a point of much importance in the formation and management of these societies. Little has yet been done to urge the necessity of every one of these clubs or lodges having a sufficient number of members to realize an average ratio of sickness and mortality; but the facts and illustrations, given in the following pages, will, it is hoped, lead to more generally correct views and better practical managements in this respect.

Much is said in the following pages, on the subject of Odd Fellow Societies, and what is written gives a faithful and accurate representation of the state of the order, at the time the 13th edition of "Observations on Odd Fellow and Friendly Societies" appeared. Since that time, important changes have taken place in the government and management of the lodges, although but little alteration in their financial condition, and it is, however, right that these financial improvements should be pointed out.

At the A.M.C., held at Preston, in May 1853, a new scale of initiation and an increased ratio of contribution was adopted, for all members admitted into the Unity after the 1st August, 1853. The following is the 145th general law then adopted and still in force in the Order:—

"That no person of improper character, nor any one under the age of 18 years shall be made a member of this order, *or any person be allowed to be a member of two lodges in the Unity.* Any member who proposes a person contrary to this law shall be liable to be fined twenty-one shillings, and not less than ten shillings and six-pence, whether the person proposed be admitted or not. The charges for initiation to be as follows:

|                      |    |       | £. | s. | d. |
|----------------------|----|-------|----|----|----|
| 18 and not exceeding | 24 | ..... | 0  | 5  | 0  |
| 24                   | "  | 27    | 0  | 7  | 6  |
| 27                   | "  | 30    | 0  | 10 | 0  |
| 30                   | "  | 32    | 0  | 15 | 0  |
| 32                   | "  | 36    | 1  | 0  | 0  |

And every member initiated, in accordance with the above scale, shall pay the following annual payment or contributions in addition to the usual contributions paid by other members.

|    |                       |                                | £. | s. | d. |
|----|-----------------------|--------------------------------|----|----|----|
| 18 | and not exceeding 22, | additional annual Contribution | 0  | 0  | 0  |
| 22 | „                     | 24                             | 0  | 0  | 6  |
| 24 | „                     | 27                             | 0  | 2  | 0  |
| 27 | „                     | 30                             | 0  | 3  | 4  |
| 30 | „                     | 32                             | 0  | 4  | 3  |
| 32 | „                     | 33                             | 0  | 4  | 5  |
| 33 | „                     | 34                             | 0  | 5  | 8  |
| 34 | „                     | 35                             | 0  | 6  | 7  |
| 35 | „                     | 36                             | 0  | 7  | 6  |

And districts shall have discretionary power to admit persons above 36 years of age, upon payment of £.1, and the yearly contributions of the lodge, together with the additional annual payment of 7s. 6d. for each and every year the age of the person proposed exceeds 36 years. Deaf and dumb persons may be admitted members of the Order."

The consequence of the adoption of this general law is that all members admitted after the 1st of August, 1853, shall, in order to be entitled to the benefits specified in page 498, *seq.* and which may be fairly said to represent the average amount of benefits provided for by the members of the Unity, namely, an allowance of 10s. per week during sickness, a payment of £.10 at the death of a member, and £.5 at the death of a member's wife, have to contribute according to the following scale:—

| Age at Entrance. | Yearly Contribution<br>= (a) | Initiation Fee<br>= (b) | Equivalent Annual Contribution. |
|------------------|------------------------------|-------------------------|---------------------------------|
|                  | £. s. d.                     | £. s. d.                | £. s. d.                        |
| 18               | 1 1 8                        | 0 5 0                   | 1 1 11                          |
| 19               |                              |                         | 1 1 11                          |
| 20               |                              |                         | 1 1 11                          |
| 21               |                              |                         | 1 1 11                          |
| 22               | 1 2 2                        | 0 7 6                   | 1 2 5                           |
| 23               |                              |                         | 1 2 5                           |
| 24               |                              |                         | 1 4 2                           |
| 25               |                              |                         | 1 4 2                           |
| 26               | 1 3 10                       | 0 10 0                  | 1 4 2                           |
| 27               |                              |                         | 1 5 5                           |
| 28               |                              |                         | 1 5 5                           |
| 29               |                              |                         | 1 5 5                           |
| 30               | 1 4 11                       | 0 15 0                  | 1 6 9                           |
| 31               |                              |                         | 1 6 9                           |
| 32               |                              |                         | 1 7 0                           |
| 33               |                              |                         | 1 9 3                           |
| 34               | 1 6 0                        | 1 0 0                   | 1 10 4                          |
| 35               |                              |                         | 1 10 4                          |

That the effect of the admission of future members into the Order on this scale may be fully seen, and the extent to which the observations made in pp. 497-529, *seq.* will be thereby modified, let a parallel case to that discussed in page 498 be considered. It is there shewn that, according to the data furnished by Mr. Ratcliffe in his very able and valuable report, and deduced from the actual experience of the Manchester Unity itself, the contributions which should be paid by members aged thirty-two (which, according to Mr. Ratcliffe's report, was nearly the average age of the members), in order to provide the precise benefits above specified, is the sum of £.1 18s. yearly; while the actual amount required by the above table, which represents the rates adopted at the annual meeting held at Preston in 1853 is only £.1 6s. and making allowance for the entrance fee of £.1, this contribution is raised to no more than £.1 7s. yearly, shewing, even according to the actual experience of the Order, an annual deficit on each member's contributions of no less than 11s. or, in other words, the scale of contributions in the Preston table would need to be augmented upwards of *forty* per cent. to fully provide for the benefits promised to the members of the Unity.

It will also be seen from page 498 *seq.* that the contributions according to scale No. 1, as prepared by the Board of Directors for the use of lodges in the Unity, and which is still applicable to all the existing members who have been admitted prior to August 1853, equivalent to £.1 2s. 9d. annually, to provide the same benefits; and, consequently, that scale requires an increase of 15s. 3d. yearly, or about an addition of sixty-seven per cent. to render their contributions commensurate with the benefits promised to this class of the members, who, at the commencement of that year were good on the books, numbered no less than 230,226. It is here evident that so far as all the older members are concerned, the relation of their contributions and benefits remains unaltered from the state of things represented in the following pages. It has, however, just been shewn that the New Scale of Contributions for age thirty-two exhibits an annual deficit of *forty* per cent. From data, however, which will be immediately presented, it appears that the average age of the members admitted to the Unity during the triennium 1853-5, was twenty-three years, and at this age, according to Mr. Ratcliffe's data, derived from the experience of the Order itself, and developed in Table Z, page 424, and Tables AU, AV, AW, and AX, pp. 494-6, *seq.* it will be found that the annual contributions required for the benefits already specified is the sum of £.1 8s. 6d. while that according to the Preston Table, after making allowance for the value of the Initiation or Entrance Fee, is only £.1 2s. 4½d. being a deficiency of 6s. 1½d. yearly; and, therefore, to make the table at that age self-supporting, the yearly payment would require to be increased upwards of twenty-seven per cent. To this extent will the contributions of all present and future members admitted under the Preston scales be deficient, while the contributions of all those admitted prior to August 1853 will be deficient to the alarming extent of sixty-seven per cent.

It is impossible, with any shew of reason, to deny these conclusions. They are derived directly from the experience of the Manchester Unity itself; but had I quoted from my own previously published data, as appearing in the other tables of this contribution, and already fully discussed, results almost precisely similar would have been obtained. There are few researches in the domain of vital statistics in which two independent investigations in different fields of inquiry have produced results so strikingly confirmatory of each other.

It may be important to shew for quinquennial ages the relation between the two scales now mentioned, and the rates deducible from the experience of the Order, which are necessary to provide the same benefits.

| Age. | Yearly Contributions now required from Members who entered the Unity |    |    |                     |    |    |
|------|----------------------------------------------------------------------|----|----|---------------------|----|----|
|      | Prior to August, 1853.                                               |    |    | Since August, 1853. |    |    |
|      |                                                                      |    |    |                     |    |    |

An examination of the preceding figures will satisfactorily shew the manner in which the financial resolutions of the Preston A. M. C. will affect the condition of the Order. Unless an immense number of the older class of members should secede from the Unity, and relieve it of their liabilities, it is undeniable that the deficit pointed out in the earlier editions of this work, and fully explained in pp. 497-514, may still be held as fairly representing the perilous condition of the Manchester Unity, even at this time.

I have good reason for knowing, that it is not the opinion of the best informed members and officers of the Order, that the scale adopted at the annual meeting at Preston, in the year 1853, is high enough in its terms to provide the benefits promised under it, but it is, no doubt, as may be seen in the preceding illustrations, an improvement on those previously in use by the Manchester Unity. The fact is, as shewn in pp. 503 and 505, the Board of Management has struggled for years with the question, and are unable suddenly to carry out a thoroughly sound and amply developed system of financial reform, and looking at all the circumstances of the case, this is scarcely to be wondered at.

There can be no question whatever, that notwithstanding the recent changes effected by the Preston table, the rates and contributions required of the members are still entirely

inadequate to provide the benefits promised, and, unless some very marked improvement be made in the adjustment of benefits and contributions, the Manchester Unity can never become a great and useful provident institution. If its present scheme does not undergo such modifications as have been clearly shewn to be necessary by its own data and experience, the Unity must either speedily disappear, or continue in the unsettled, unsatisfactory, and unstable condition in which it has been for the last ten or twelve years. An examination of the Quarterly Reports of the G. M. and Board of Directors shews that in the triennium 1853-5, no less than 47,274 new members entered the Unity. This should act as a warning. The directors, as stated in page 502, *seq.* remark in one of their reports, " That the amount of initiation money received from members in 1844, being no less a " sum than £.49,382, it will be observed, on reference to the list of lodges, that our increase " of members in that year was only 21,461, and by these returns, it is clearly proved that " upwards of 40,000 members were initiated in 1844, thereby at once affirming that " upwards of 20,000 members left the Order in one year, after paying their initiation " money and contributions for a length of time. We are of opinion that the particular " attention of the members of the Order should be drawn to this important fact, with a " view of arriving at the true cause why so many leave the Order."

It would hence appear that the same lamentable state of things continues, for, notwithstanding the large number of new members joining the association, 47,274 having entered during the three years 1853-5, and, as hereafter shewn, the admissions were in preceding years in even a higher ratio, still the members have not increased since the beginning of 1844. At that date, the number of members is represented in one of the director's reports to be 251,727, and now we find, from the quarterly report for April, 1856, that, at the beginning of that year, the number good on the books was 251,008. This is, perhaps, the very worst circumstance which can be urged against the present state of the Manchester Unity. The influences must be very powerful which have caused so many members of late years to desert the Order in this wholesale manner, and is no doubt one of the reasons why many lodges have augmented their funds even with a scale of contributions, which would, under a normal and less perturbed state of membership, be ruinously low and inadequate. It happens to be within my knowledge, that when valuations of the assets and liabilities of some of the lodges have been made, that although they were found to be charging insufficient contributions for the benefits granted, still they were declared to have a surplus of assets over liabilities, and this fact was accounted for by the great number of members leaving the lodges and sacrificing their initiation money and their contributions for several years.

This fluctuating condition of membership is much to be deplored, and I am afraid it will long continue, unless by a speedy and proper adjustment of the contributions and

benefits, members are led to place greater confidence in the permanence and stability of the Order.

It is also important to contrast the condition of the Unity in respect to the number of members within the twelve years which have elapsed since January 1844, with that of the immediately preceding ten years.

In the year 1834, the number of members in the Unity was about 60,000; in January 1844, it had increased to no less than 251,727, being an absolute increment, after allowing for deaths and withdrawals, of more than 19,000 per annum; but within the last twelve years no increase would appear to have taken place, although these latter years constitute undoubtedly the period of greatest prudential progress in the history of Benefit Societies. It must be admitted, that the gigantic proportions of the Manchester Unity have attracted so much public attention to its affairs, and the question of its stability has, within recent years, been so openly and freely discussed before Parliamentary Committees and elsewhere, that it was impossible for members to repose the same confidence in the safety and permanence of the institution which they willingly lent to it during the earlier period of years.

It is highly important for those taking an interest in this great Friendly Society to understand clearly the nature and extent of the changes going on amongst the members in recent years, and the following succinct Abstract has, from the data furnished in the Quarterly Reports, been prepared for that purpose.

| Year.  | Members less than Twelve Months in arrear on the first day of the Year. | New Members initiated. | Deaths. | Lodges Suspended for non-compliance. |                    | Lodges Expelled from the Unity. |                    | Lodges Closed, by a Division of Funds. |                    | Lodges Closed by want of Funds, small Number of Members, Failure of Banks, &c. &c. |                    | Lodges Seceded from the Unity. |                    | Lodges Amalgamated with other Lodges. | Number of Members who have ceased to belong to the Unity on their own account. |

\* Good on the Books only.

It will be seen from the above figures that in six years no less than 88,033 new members entered the Unity. The number of deaths amounted to 15,425, but the large number of 52,022 members seceded from the Order from the various causes assigned

in the preceding Abstract. It has already been stated, that on the 1st of January, 1856, the number of members was 251,008, and from a succeeding Abstract, given in page xxxiii, it will be found that the new members initiated during the eight preceding years was 108,410, or about forty-three per cent. of the existing members. It is further shewn in the Quarterly Reports that on the 1st January, 1846, the Order numbered 259,374 members. This number, it will be seen, gradually fell, until on the beginning of 1853 it reached 224,441, and from that time it has increased in the rapid manner shewn in the preceding Abstract, and bids fair to reach the maximum number attained in 1846.

This great fluctuation in the members, the unprecedented number of initiations, and the equal number of withdrawals, keeps the Unity, as already remarked, in the most unsettled, unstable, and unsatisfactory condition. Were its financial arrangements placed on a satisfactory basis more confidence would be inspired, the privilege of membership would be more valued, and no doubt seceders greatly reduced in number.

For a variety of important purposes the following figures, taken from the Quarterly Reports, throw valuable light, not only on the present condition of the Unity, but the economic and moral state of the working classes generally, and they should be carefully studied by every one watching the social progress of the day. In the Contribution on Criminal Statistics, pp. 303, 369, and 403, it will be found that the period of life of highest criminal intensity is ages 21-25, and hence arises the important practical bearing of all Benefit Societies on the moral condition of the people. Those are the very ages when admission to Friendly and Odd Fellow Lodges is most easy, and the following Abstract shews that during the years 21-25 as many as 42.983 per cent. of all the admissions took place between those ages. Viewing in connection with these results the well known fact that the least criminal portion of the whole community is represented by those who attach themselves to Benefit Clubs and Odd Fellow Lodges, it is evident that by means of these societies a very powerful and most beneficial influence may be exercised over that most important section of the population whose habits are as yet unformed, who have just entered upon the period of life of greatest criminal temptation, but who are still at the same time the most susceptible of acquiring those prudential feelings which find their best expression through the medium of their own Provident Institutions. Afford a young man the opportunity of joining well organised societies, and the respect he has for the opinion of his fellow members will exercise a powerful check on his criminal propensities.

The following gives the number of members who have joined the Manchester Unity of the Independent Order of Odd Fellows during each of the eight years 1848-55.

The following is a condensed Abstract of the preceding results :—

| Ages.          | Admission in the Years 1848-55. | Ratio of Admission at each term of Life. | Ages.          |
|----------------|---------------------------------|------------------------------------------|----------------|
| 18 to 20       | 33,704                          | 31.089                                   | 18 to 20       |
| 21 ... 25      | 46,598                          | 42.983                                   | 21 ... 25      |
| 26 ... 30      | 21,072                          | 19.437                                   | 26 ... 30      |
| 31 ... 35      | 6,346                           | 5.854                                    | 31 ... 35      |
| 36 and upwards | 690                             | .637                                     | 36 and upwards |
| Total ...      | 108,410                         | 100.000                                  | Total.         |

From the preceding figures it will be seen that during the eight years, 1848-55, no less than 74.072 per cent. of all the admissions took place under twenty-six years of age, and the large proportion of 93.509 per cent. at ages not exceeding thirty.

Although it may appear, that notwithstanding the improvement in the Preston scale of contributions on the preceding ones in use, I have still presented a very unpromising picture of the present condition and prospects of the Unity ; it would, while doing so, be

wrong to conceal the fact of other important changes having taken place since the publication of Mr. Ratcliffe's valuable Report in 1850. In the earlier editions of "Observations on Odd Fellows and Friendly Societies," it was distinctly affirmed (*See* second paragraph page 527 *seq.*) that much good would flow from the publication of the results of any such investigations as that subsequently and so ably conducted by him. It is, therefore, most satisfactory to find this view of the matter practically verified.

Since that time, as already stated, the large majority of lodges has improved their rates of contributions, either by increasing the periodical payments, or in lessening the benefits by reducing the amount of funeral gift, and limiting the time to which members are to be entitled to full sick allowance. This latter step, on many grounds objectionable, has only the merit of bringing the contributions and benefits nearer to each other in value. Mr. Ratcliffe, in the Appendix to the Quarterly Report for January 1853, has actually calculated specimen Tables for the lodges in which it is assumed that the benefits in sickness will finally be reduced to three shillings per week, and, in old age, to two shillings and sixpence weekly. It can however never be meant to reduce Odd Fellow Lodges to so degraded a position; the title of the Order must be altered first. It could never be called an "Independent Order" by thus making it a mere receptacle of infirm paupers for the workhouse. In no instance should the allowance granted to members be permitted to fall below such sum as would be self-supporting. If the rates of contributions be inadequate for that purpose, the proper remedy is to increase them. I am also given, on the best authority, to understand that there is now not a single branch of the Unity which does not keep its management expenses separate and distinct from the funeral and sick-gift funds. This is, indeed, an unmistakeable advance in the right direction. The Unity is also now a registered society. From the Quarterly Report for April 1856, it appears that, at the beginning of that year, "two hundred and ninety-five districts, containing 190,414 members, have registered their laws, and one hundred and thirty-eight districts (including foreign and colonial), containing 60,526 members, still remain unregistered as districts, but many lodges in those districts have availed themselves of the privileges conferred by the Friendly Societies' Act, and have registered their rules." All these societies must, therefore, make quinquennial returns to the Registrar of Friendly Societies, and the preparation of these is certain to lead to inquiry on the part of members, inquiry to discussion, discussion to clearer views and more carefully formed opinions, and thence giving birth to wiser laws and regulations. Some lodges are also adopting the plan of having periodical valuations of their assets and liabilities—a thing some years ago altogether unheard of amongst them. This, if general, would lead to the best results; but, if deferred until too late a period, lodges may find it impossible to recover themselves from the effects of past deficiencies.

Recently there has been revived, in one or two influential quarters, proposals to establish what are generally termed Yearly Societies. These will be found alluded to in Question No. 477 of Lord Beaumont's Report, and are undoubtedly the most objectionable of all sorts of Benefit Societies, as the members are simply required to meet the current risks of the year; they do not recognise the principle which is the foundation of all true Friendly Societies,—that of making a provision in youth for the winter of life. This is a principle which the physical laws of nature and the necessities of civilisation impose on the promoters of every Friendly Society, and it may be easily shewn that if an attempt be made to evade it, the formation of a permanent Friendly Society is impossible. Let it be assumed that a club is formed on the bases of the contributions providing for the necessities of the year only, and that, in the first instance, the members consist chiefly of young men, ranging from twenty to thirty years of age; on referring to Table E. pp. 26–7, and Table V. page 409, it will be found that, for the average of the first period of ten years a contribution of about nine shillings, from year to year, would suffice to grant sickness allowances of ten shillings a week to those who are invalided. During the next ten years, when the ages of the original members of the society range from thirty to forty, the contribution for the same benefit will need to be only slightly raised, namely to ten shillings from year to year. Such societies usually balance their affairs at the end of each year, and then begin *de novo*; but whether this be done or not, and a fresh election of members takes place, is immaterial for the purpose of the following illustration. On referring to column (8) of the Abstract on page xxiv preceding, it will be found that from five to fourteen per cent. of all the sickness experienced by members at the periods of life now under review is sickness protracted beyond the period of one year's duration. Again, assuming the society to go on for another period of ten years, when the original members shall range from forty to fifty years of age, the contributions from year to year, to provide the same benefits will require to be increased to about sixteen shillings, but in this decennium the sickness which shall be experienced after twelve months duration will amount to from about nineteen to upwards of twenty-five per cent. of the whole sickness to which the society is liable, and the sickness which shall actually be experienced after two years invaliding is no less than from ten to fifteen per cent. of the whole. Hence the question arises, would the healthy members of a society thus constituted consent to so severe and almost permanent a burden? Would they not, when balancing their books from year to year naturally complain and object to the renewal of the membership of those who are receiving so much of the proceeds of their contributions? For example, according to Table NN, page 446, *seq.* five per cent. of the members during the decennium now under consideration would, in lieu of their small contributions, have received a minimum £.26 each, and some of them three or four times that amount, but in the next decennium fourteen per cent. of all the members would be in this condition, and the ratio,

as shewn in Table NN, going on rapidly increasing. Yearly Societies have not, however, existed long enough to go through this ordeal. In the ten years we are now considering, when the ages of the original members range from fifty to sixty, a further, and perhaps a more serious practical difficulty is obvious. To provide for the current liabilities, the contributions would need to be nearly doubled, or £.1 10s. yearly, and those members who pass on to the next decennium would have to pay the impossible sum, for the time of life, of four guineas a year, exclusive of the payments necessary to make provision for funeral allowance to the member or his wife, pensions or annuities in old age, and the expenses of management of the society.

It is scarcely necessary to argue that from the physical impossibility of escaping numerous cases of protracted sickness at all periods of life, and the very high ratio of general sickness at the more advanced ages, rendering it impossible for working men at that time to provide for the current liabilities out of their earnings, the management of a "Yearly Friendly Society" is impracticable, unless at the younger ages; hence exists the usual rule of excluding from such societies all persons from membership beyond a given age, say forty or fifty-five. To encourage the formation of such societies would be to inflict a severe blow on all those who might be tempted to join them. They are destructive of the real purpose for which Benefit Societies were originally intended; inasmuch as the old and infirm, for whom Provident Institutions are most destined to do good, cannot avail themselves of them, and they certainly stand in the way of persons entering better constituted societies, for they draft off members in the vigour of life, and only retain them until such time as when, from advanced age, the necessarily high scale of contributions practically excludes them from admission to the best class of Friendly Societies.

The experience of all the best constituted societies demonstrates the impracticability of the working classes joining them in any considerable numbers, except at the younger periods of life—under the age of thirty. From that age to forty, owing to the rapidly-increasing rates of contributions, the numbers are very small, and beyond the age of forty, the numbers become exceedingly limited. Even in the Odd Fellow Lodges, possessing many social inducements to membership, this is borne out in a remarkable manner by the facts set forth in the Abstract in page xxxiii preceding. The liability to sickness and death is at a comparatively low ratio at the younger ages, and unless members, by entering a society at early life, pay rates of contributions more than equivalent to meet the evils of the hour, a time will arrive when the sickness with which they are overtaken is beyond their resources. It is, therefore, necessary to store up in youth for the vicissitudes of old age, and on this principle every Friendly Society, worthy of the name, has been founded.

Much has been said of late on the necessarily inherent instability of Friendly Societies, and, on their presumed want of permanence, various suggestions have been

made, by which it is proposed to transfer to the management and responsibility of the Government some of the most important branches of their transactions and benefits. A deal of information is given in pp. 408-530 on the various circumstances which influence the permanence of Friendly Societies. A patient perusal of those pages will distinctly shew that there is no institution of the day connected with the social progress of society which can be regarded, in a financial sense, so safe and permanent in its character as a Friendly Society, conducted on the principles therein pointed out, and now fully recognised by every one experienced in the management of this class of Provident Associations, conclusively proving that they offer the most undoubted security which can be conceived for the fulfilment of their engagements, their duration, and their permanence. It is believed impossible to point out a single instance in any part of the country whatever of the failure of a Friendly Society in which one or all of those conditions of stability and safety have not been violated.

These conditions may be briefly recited.

In the first place it is necessary, as fully shewn in pp. 514-21, *seq.* that every society should consist of members sufficiently numerous to realise the average results anticipated in the calculations on which its tables of contributions and benefits are founded. If this principle be not attended to, and the societies are small, the best and most skilful calculations may be insufficient to maintain their solvency. It might happen that rates very much in excess of what might be necessary in a large institution would, owing to adverse fluctuations, be totally inadequate to provide the benefits promised to the members; or, on the other hand, rates that would be ruinously low in a society of considerable magnitude, might, from the prevalence of favourable ratios of sickness and mortality, prove quite ample, and even leave a surplus in a society of a limited number of members. This case is exceedingly well put in the Report of the Preston District Sick Union (*see* pp. 515-19, *seq.*), and the various Quarterly Reports of the G. M. and Board of Directors also contain frequent allusions to societies breaking down or closing owing to adverse results from small numbers, while others, in which little sickness has been experienced, from the avarice and cupidity of the members, inducing them to pocket the Surplus Funds. In the Report for April, 1855, it is stated that—"Those who have paid  
 " attention to the average rate of sickness, when the experience of few members has been  
 " obtained, must have been struck with the very large ratio in some instances experienced,  
 " in other instances with the small rate of average sickness, and, when it is considered the  
 " number of lodges in the Unity having few members, it is surprising that more lodges are  
 " not compelled to close, by experiencing far more than the average rate of sickness.  
 " During the year 1854, twenty lodges have joined other lodges; thus, instead of existing  
 " as forty separate and distinct lodges, they only form twenty lodges in number, and  
 " causing the number of lodges in the Unity to be diminished by twenty." "Many of

“ the lodges that have been closed, during the year 1854, have had considerably less than  
 “ the average amount of sickness amongst their members, and this for a considerable  
 “ period of time, and which has enabled many of them to realise funds of £.10 per  
 “ member, others more, and one as high as £.25 per member; in some few other  
 “ instances they have experienced more than the average sickness, and their funds have  
 “ been reduced; one lodge only closing for want of funds to pay their sick members.  
 “ When it is seen that twenty lodges, containing 539 members, have closed during the  
 “ year, it will be very apparent, that with the average number of members forming these  
 “ lodges, that when one or two members fall sick, in so few a number, their funds must  
 “ soon become exhausted.” In fact, unless the number of members in a society be  
 considerable, there can be no security for its stability, however great the skill and  
 judgment exercised in its management in other respects. Inattention, therefore, to this  
 one element is of itself sufficient to produce failure in Friendly Societies.

In the second place, as pointed out in pp. 439 and 527, a periodical investigation  
 should be instituted into the state of the society's affairs. Such periodical inquiries would  
 afford the means of correcting any misconceptions which may have existed either at their  
 formation or at any subsequent stage of their progress, in respect to the rate of sickness  
 and mortality to which they are presumed to be liable; and the actual experience of each  
 society would thus be brought to bear upon the financial adjustment of its assets and  
 liabilities. These investigations should be made at not greater intervals than five years.  
 One great mistake often made by the promoters and managers of small societies, is that  
 they conceive if a particular society is eminently successful under a given scale of  
 contributions and benefits, that those who are residing in another district, and living  
 under different influences, cannot do better than follow the example of their neighbours  
 in the adjustment of the contributions and benefits. This impression is natural enough;  
 but no conclusion has of late years been better established by practical research than the  
 fact of the great disparity which exists between the ratios of sickness among societies  
 established even in adjacent districts. This has been fully shewn in pp. 408-68, even  
 when the number of members in the societies is sufficiently large to realise the average  
 amount of sickness peculiar to the district. Hence, the necessity and the advantage of  
 regulations imposing on societies the duty of periodical investigations into their affairs;  
 for by this means, actual experience, the most valuable of all teachers, is made operative  
 in their future conduct and management. It is well known that in the county of  
 Wilts, (see page 437) large and well-conducted societies have been subject to an  
 unusually low ratio of sickness; that in Somersetshire, other societies, equally well-  
 conducted, have been subject to an unusually high ratio of sickness; while in the  
 intermediate districts of Devonshire, the ratio of sickness actually experienced by a large  
 and well-managed society has proved very different from those which prevail in the other

two counties. It will also be found, that comparing the sickness experienced in two agricultural counties, Essex and Hampshire,—that in Essex, the sickness is unusually high; while in Hampshire it is considerably under the average. The causes of these variations are fully discussed in the following contributions. Similar differences will be found to prevail in the experience of societies in different manufacturing towns, examples of which are given in pp. 429–38. Hence, the imperative necessity of periodical investigations, such as those herein suggested, in order to maintain the solvency and permanency of Provident Societies. As already stated, many lodges in the Manchester Unity have recently become alive to the advantages arising from periodical examinations of their assets and liabilities, and so great was the importance attached to these investigations that it was actually rendered compulsory on societies enrolled under the 9 and 10 Vict., c. 27, although unwisely omitted in all the subsequent Acts.

In the third place, there should be a regulation by which every society shall have a separate and distinct account kept of the receipts and disbursements made in respect of each benefit or fund. From the passing of the 8 and 9 Vict., c. 27, this was compulsory on all societies subsequently enrolled, until repealed by the 18 and 19 Vict., c. 63. The advantage of such a regulation is, that if the financial condition of any particular fund or benefit is at fault, the error would be more easily discovered than if the whole receipts and disbursements of the society were kept collectively. It might happen for instance, that while all the other funds of a society were well regulated, so far as their contributions and benefits were concerned, that the sickness benefits were making ruinous inroads on the society's assets; but from the accounts being kept in the aggregate, this evil may not be perceived until it is too late to apply a remedy. If, however, the suggestion here offered had been adopted, it is evident that all such untoward influences would have manifested themselves at a much earlier period, and when corrections could have been in time applied to restore the fund to a healthy and normal condition. Such societies have unfortunately been too often assumed to be in a prosperous condition, from the mere fact of their accumulated capital having kept increasing year after year. But as no portion of the money received for superannuation allowances and other deferred benefits should be touched for a long period of years, this fact was lost sight of in the aggregate system of accounts, and the monies belonging to them too often infringed upon for payments on account of the sickness fund, owing to the inadequacy of its contributions.

It can be abundantly proved, by the citation of numerous well known instances, that many societies would have been saved from ruin and dissolution, by the early adoption of such a rule as the one now suggested; while in many other instances in which the breaking up of societies did not ensue, the hardship of one class of members supporting another, between which there was no common interest, would have been avoided.

The fourth precaution necessary to be observed is never to allow any member to subscribe for a sickness allowance greatly exceeding the average of the benefits allowed to all the members collectively; and never, in any instance, to permit a member to subscribe for a sickness allowance which shall exceed two-thirds or three-fourths of his usual or average earnings while following his ordinary avocations. The enforcement of this condition would form a great protection in the administration of the society's affairs, and maintain a healthy moral tone of action amongst the members. Such a rule simplifies the administration of the sickness benefits, and is conservative of the society by placing the members in a better position in regard to its management. The society's prosperity is greatly promoted by the practice of never admitting any members to subscribe for a greater sickness allowance than will always, irrespective of other conditions, maintain a healthy inducement in the minds of sickness claimants to return to their occupations as soon as they possibly can with safety, rather than linger on the funds. Nothing can be more injurious and detrimental, both to the members and the society, than to permit of sickness allowances being granted that shall closely approximate to the member's earnings. There is scarcely any consideration by which it is possible to justify such a proceeding. The best securities for a society's success would be afforded in the adoption of this regulation.

A careful consideration of the four conditions now urged will shew that their practical effect is to maintain a constant adjustment between the contributions made by the members under all varying circumstances, and the liabilities they entail on the society. Were these four leading principles strictly observed in the management of Friendly Societies, failure is next to impossible. Let them be practically adopted and it is difficult to conceive any human institution more beneficial and permanent.

It is not therefore to be assumed, as has of late been said in various influential quarters, that Friendly Societies are in their nature essentially instable. An attentive consideration of their history will satisfactorily shew the wonder is, that with so little information, until quite recently, of the real nature and extent of their liabilities, more of them have not broken down. It has been too much assumed, by even the educated classes and not a few of those distinguished persons who have identified themselves publicly with the interests of these societies, that at best they were but mere pot-house schemes and temporary expedients as adjuncts to a small parish or congregation, simply calculated to assuage the evils of a day. It has remained for the working classes themselves to demonstrate that their Benefit Societies are capable of accomplishing much beyond this, and those must be indifferent spectators indeed of the social progress amongst the industrious community who cannot clearly discern that through one form or other of these institutions, whether in the shape of the ordinary Friendly and Benefit Society, the Odd Fellow, Foresters, and Druid Lodges, the Rechabite Tents, and other

description of Benefit Clubs, the hard working prudential people of this country have already begun to work out in good earnest their own regeneration and independence. These associations are therefore certain, before long, to become engrafted with all the essential elements of stability and permanence which have just been pointed out.

No doubt Benefit Societies have suffered from many serious evils, but these will be found to have nearly all arisen from ignorance and inexperience. More light, however, has now dawned upon them. Even our Assurance Institutions, which are more simple in principle and much less difficult in management, have been any thing but free from grave objections, but no one attempts in consequence to transfer their business and their responsibilities to the Government of the country. Let us see therefore the merits of the proposal made, on the plea of the insecurity of Friendly Societies, that the working people of this country should purchase deferred annuities and pensions from the Government, under the 16th and 17th Vict., cap. 45.

Apart from the objection so often urged, that the people have always shewn a great aversion to have any dealings in connection with their Benefit Clubs with the Government, and hence the immense multitude, hitherto, of unenrolled societies, and the striking failure of the corresponding attempt to sell Government Annuities to them under the 3rd William IV., cap. 14. It is of the first importance that the fact of this failure on the part of the Government should be thoroughly understood, especially by those now endeavouring to ingratiate into the favour of the people the recent Annuity Act. Great efforts were originally made by the Government officials to render the scheme successful. It was arranged that through the medium of savings banks such annuities could be purchased, and that in any parish or place in the United Kingdom where no savings bank was legally established, it was lawful to establish a society for carrying the provisions of the Act into execution, and that annuities of not less than £.4 nor more than £.30 per annum, might be secured, and the annuities might be either "immediate," "deferred," or "temporary annuities for a certain number of years." In this latter respect the former Act was more comprehensive than the recent one. Provision was also made that the consideration money for the annuities may be paid either in one sum in the first instance, or by weekly, monthly, quarterly, or yearly instalments, as may suit the convenience of the purchaser. In this respect also the former Act had an advantage over the present one, for it was provided, that if the contract were for a deferred annuity, to be purchased by annual payments, such annual payments must be made to the Commissioners yearly, although for the convenience of the purchaser the money might be received from him by the manager in weekly, monthly, or other instalments. The recent Act repeals the former one and contains no such provision. To the working man the existing Act is further inconvenient, as the fractional parts of one pound of annuity will not be granted, whereas this rule was in the former one limited to the fractional part of

sixpence. It will likewise be found that the annuities were granted on more liberal terms under the 3rd William IV., cap. 14, than under the recent Act, 16th and 17th Vict., cap. 45.

The following shews the terms required to secure an annuity of £.20 per annum, or not quite eight shillings weekly, according to each Act.

| Age at Purchase. | Purchase Money of Annuity deferred 25 Years. |                            |          |          |                       |                            |                    |          |           |  |  | Age at Purchase. |

| 50 ... 51        | 45 10 0                                      | 52 11 8                    | 60 18 4  | 2 13 6   | 3 0 0                 | 3 8 4                      |                    |          | 50 ... 51 |  |  |                  |

It will be thus seen, that under the former Act the annuities were granted on much more favourable terms. In the above examples, the recent Act exacts an increase on the purchase money, by single payment of 18·053 per cent. in the case of males, and of no less than 35·312 per cent. for females; while the increase by annual payments amounts in the case of males to 13·182 per cent., and in that of females to 29·603 per cent.

Taking all these matters into account, it is evident that the present Act offers very inferior inducements to annuitants than that which has been repealed; but notwithstanding, the former Act, after having been in force for twenty years, entirely failed in the accomplishment of the object intended by its enactment. It is stated that in the whole of that period, only 2043 members have availed themselves of its provisions. The fact is, the members of Benefit Clubs have a strong, and it may be said in this instance, a well and justly conceived dislike to Government interference in such matters. Were there no other reason than the delay and annoyance to which working men, or the societies representing them, would be put by the circumlocutory formula through which all such transactions must necessarily pass, whenever undertaken by the Government of the country, there would be sufficient reason to render the operations of the Act unpopular and therefore unsuccessful. But there are still more formidable reasons to be advanced against it. Deferred annuities constitute one of the class of benefits for which provision can be more successfully made by Friendly Societies than any other. In the first place,

an examination into the state and condition of health is unnecessary, for if the annuitant's health be bad, that is in favour of the society. In the second place, the administration of the benefit is one of the most simple: it does not require the constant watching and medical scrutiny and skill necessary in the administration of the sickness benefits. And in the third place, the financial operations connected with it are also of the simplest kind possible. In the management of the sickness and death allowance benefits, a portion of the funds must be always kept on hand, or at immediate call, to meet the constantly occurring claims, and the consequence is, that unless a calculation be entered into, on the plan recommended in pp. xxxviii and xxxix, *ante*, to be made quinquennially, it is impossible to tell with any precision whether undue inroads are being made on the funds of those benefits or not. In regard however to deferred annuities, the case is very different, for every farthing in the shape of contributions must be husbanded and improved at interest, and remain untouched until the time arrives which is fixed for the annuitant to receive his pension; and even then, unlike the case of the sickness benefit, nothing more is needed to be established than the fact of his identity. All the trouble of visitation and medical scrutiny, to determine whether the sickness is feigned or otherwise, is unnecessary. The system of accounts and the whole management are therefore as simple as possible. It is, in consequence, difficult to conceive how any disaster could befall this branch of a society's affairs, always supposing the management subject to such of the four conditions, already mentioned, as may affect it. This statement is not a mere speculative opinion, for while the failure of so many sickness clubs has to be lamented, a great number of annuity societies, established even when such matters were but imperfectly understood, can be pointed to as having been eminently successful; with periodical examinations of their affairs, it is next to impossible to conceive how, especially at the present time, when the laws of mortality are so much better understood, that it could be otherwise.

But in pp. 524-6 other important reasons are given why Sickness Societies should grant Deferred Annuities. The proper introduction of annuity schemes into Friendly Societies, and particularly into large societies, such as the Christian Mutual Provident, the Western Provident, and all other large and county societies, which extend over considerable districts, as well as a gigantic institution like the Manchester Unity, would possess advantages of a high and important character in equalising the risks of different districts and occupations, and enabling the societies to adopt something like uniform scales of contributions and benefits by which the liabilities from sickness and annuities shall have a constant corrective influence on each other.

Independent, however, of the attempt to engraft the recent Annuity Act on Benefit Societies, and thereby disturb the peaceful and improving condition which, for several years, in spite of many disturbing influences, they have been gradually assuming, it

cannot be denied that, in respect to them there has been a great deal of over-legislation. A curious and somewhat amusing proof of this will be obtained by a perusal of pp. 8-36 of the Appendix to the First Report of the Registrar of Friendly Societies in England. It will be found that between 1793 and 1855 no less than twenty-three Acts have been passed affecting them; and in the ten years, 1846-55, as many as ten Acts, or one per annum. To know how instable the legislative opinion is on such matters, the Analysis of the 9 and 10 Vict. c. 27, 13 and 14 Vict. c. 115, and 18 and 19 Vict. c. 63, will well repay a perusal. The constant change of object, scope, and privilege, under these three Acts has done much to retard the development of the larger and better conducted class of Friendly Societies, established within the last few years.

It is hoped the present publication, by giving new assurance to the whole class of provident institutions, will, in some measure, counteract this influence, and give a fresh impetus to their progress. The evident tendency in the minds of public men at the present time is to a conviction that the working people can, by legislative processes, be constrained impulsively to the adoption of prudential and saving habits. No mistake, however, is more fatal to the success of the institutions themselves. All that is needed to be done is, to enable the members of them, as between themselves, and also as between them and third parties, to sue and be sued, in a cheap and expeditious manner, and leave all the rest to themselves. Their experience, judgment, interest, and tact, will soon discover the most beneficial modes of management, without Government patronage or supervision. The members of Friendly Societies in this country form a much more important class socially, intellectually, and politically, than is generally supposed. To strengthen those habits of prudence and forethought, which they already manifest to a considerable extent is a work of time, a gradual process, almost entirely dependent on themselves. Calm deliberation can alone help them, and it is trusted that the large amount of information now submitted for their help and guidance in the management of their societies will aid to bring about that happy consummation of their interests which even those of wealth and exalted station may behold with pleasure, saying—

*“ Quam bonum et jucundum est habitare fratres in unum.”*

THE PEOPLE'S PROVIDENT SOCIETY,

2, WATERLOO PLACE, LONDON,

24th February, 1857.

## DURATION OF LIFE IN ENGLAND AND WALES.

THE best record of the General Mortality in England and Wales is contained in the Annual Reports of the Registrar General. So far as relates to the number of deaths in the entire community, more complete returns could not be hoped for.

The 5th Report of the Registrar General contains a table of the Expectation of Life, calculated on the mortality of the year 1841. The census of the population having been taken in that year, offered a ready means to determine the value of life for that period; but as the results of the mortality for several years would undoubtedly form a broader and more satisfactory basis on which to found a measure of the duration of life in this country, it is proposed to calculate a table on the 2nd, 3rd, 4th, and 5th Reports of the Registrar General; omitting the 1st Report, that any imperfections incidental to the early management of the Registers may be avoided. It is evidently necessary to ascertain the exact amount of population living at various ages in the country, during the periods of time to which the returns of deaths relate, before results can be obtained, shewing the ratio of the population dying at the respective ages.

Previous to the population being calculated for the mean time of each period embraced in the 2nd, 3rd, 4th, and 5th Reports, it will be necessary to apply a correction to the enumeration of the population at the period of the Census.

In 1841, the ages of 35,408 males and 11,472 females, or .456 per cent. of the one, and .141 per cent. of the other, were not given. In the registration of deaths, the ages of a certain proportion are also omitted; and if the ratio were the same in both cases, those whose ages were not specified might be left out, as the omission of the one would be corrected by the omission of the other; but it happens that, in the returns of deaths over the entire four years referred to, the number of males whose ages were not specified

was only 1,650, or .235 per cent. of the whole; and of females 896, or only .132 per cent. of the whole female deaths. Independent corrections will, therefore, have to be applied to each class of results.

Let  $a$  = population whose ages were ascertained,

$b$  = total population, and

$x$  = the number enumerated at any particular period of life; and let

$\lambda b - \lambda a = \lambda y$ , then

$\lambda y + \lambda x = \log.$  of the actual number alive at the period of life  $x$ , provided the age of every person had been ascertained.

This correction having been made for the unenumerated ages in the respective censuses of 1821 and 1841, the results obtained form the 2nd, 3rd, 5th, and 6th columns of TABLE A.

TABLE A.

Corrected Enumeration of the Population of England and Wales for 1821 and 1841; with the Annual Rate of Increase during the Intermediate Period.

The 2nd, 3rd, and 4th Reports of the Registrar General gave the number of deaths in the year preceding the 30th June, 1839, 1840, and 1841 respectively; and the 5th Report gave the deaths for the year ending 31st December, 1841. The next step required was to determine the population alive at various ages for the mean time of each of the given periods, that is, the population at the various terms of life in England and Wales on the 31st of December, 1838, 1839, 1840, and 30th June, 1841; and the following method was employed:

$\lambda\pi + \left(\frac{\lambda\pi - \lambda\beta}{20}\right)\theta = \log.$  of the population at the given term of life for the mean time of the period required, in which

$\beta$  = the corrected population at the given age on the day of the Census in 1821,

$\pi$  = the same for 1841, and

$\theta$  = the period elapsed in years and days between the given period and the day of the Census in 1841.

The population for each of the periods being obtained in this manner for every term of life, the combined results form columns 2nd and 5th of TABLE B.

It might have been deemed sufficient to have made the expression  $\frac{\text{Log. } \pi - \text{log. } \beta}{20}$  represent the rate of increase on the general population for all ages; but a glance at columns 4 and 7 of TABLE A will shew the necessity of obtaining an independent value to this expression for each term of life; for, by adopting  $\frac{\text{Log. } \pi - \text{log. } \beta}{20}$  as the rate of increase for every term of life, it would have produced a difference in the male population at ages 20 to 30 of 42108 in TABLE B, or, in other words, an apparent decrease of mortality at that term of life; and consequently, at some other terms, opposite errors in the results would be produced.

Corrections, precisely similar to those applied to the enumeration of the population, were made on the registration of deaths; and the final results for the four years referred to are given in columns 3rd and 6th of TABLE B.

It may be observed here, that as the deaths happening in the last half of the year forming the fourth period of the Registrar General, and those taking place in the first half of the year forming its fifth period, are identical, they will of course be included twice in the results now referred to; but as the population has also been taken for the mean of both periods or years, the proper relation is maintained between the population and deaths.

The preceding step was rendered necessary, from the Registrar General having changed the period for his Annual Report from the 30th June to the 31st December, without having, at the time of making the change, distinguished the deaths belonging to each half year.

All the preceding corrections having been applied to the population and deaths, the combined results form TABLE B, the 4th and 7th columns of which shew the mortality per cent. at the various terms of life for each sex in England and Wales during the four years referred to, and under that form constitute a complete measure of the value of life, during the same period, in the general population of this country.

TABLE B.

ENGLAND and WALES.—Total of the Population as calculated for the 31st December in the years 1838, 1839, 1840, and 30th June, 1841; with the Sum of the Corrected Deaths for the corresponding years as given in the 2nd, 3rd, 4th, and 5th Reports of the Registrar General; and the Mortality per cent. during that period.

| Ages.            | MALES.      |         |                     | FEMALES.    |         |                     | Ages.            |

The results now described in columns 4th and 7th of TABLE B, were made to represent the rate of mortality at the mean age of that period of life opposite to which they are placed; intermediate terms were then found by the method of third differences, as fully explained in a subsequent portion of this contribution, and the whole was subsequently corrected as follows:

Let  $\delta_1$  represent the first term;

$\delta_2$  ... second;

$\delta_3$  ... third;

$\delta_n$  ... the  $n^{\text{th}}$  term; then

$$\frac{\delta_1 + \delta_2 + \delta_3 + \delta_4 + \delta_5}{5} = \delta_3$$

$$\frac{\delta_2 + \delta_3 + \delta_4 + \delta_5 + \delta_6}{5} = \delta_4 \quad \text{And}$$

$$\frac{\delta_{n-4} + \delta_{n-3} + \delta_{n-2} + \delta_{n-1} + \delta_n}{5} = \delta_{n-2}$$

The adjusted results thus obtained form columns 4 and 9 of Table C, and may be considered a fair expression of the rate of mortality at the respective ages opposite to which they are placed in the Table. Columns 2nd and 3rd, 7th and 8th in the same Table, shew, out of 100,000 persons attaining the age of ten years, the number living to each subsequent year of life, and also the numbers dying in each successive year of life. Columns

[5 and 10

| 105  | 3       | 2      | 66.667              | 1.500               | 105  | 4        | 2      | 50.000              | 2.000               | 105  |
| 106  | 1       | 1      | 100.000             | 1.000               | 106  | 2        | 1      | 100.000             | 1.000               | 106  |

5 and 10 contain the reciprocals of columns 4 and 9, and represent the specific intensity of life at each age. Male and female life will each be found to attain its highest specific intensity at the age of 14. It will also be seen that male life possesses a much higher specific intensity than female life up to the age of 25 inclusive; from that to the age of 38 the difference is very little, but that generally in favour of male life; and that from 38 upwards to nearly the extreme of life, the scale turns in favour of female life, and the specific intensity is higher throughout. At the age of 50 the two sexes attain their balance, the numbers surviving of each, from the age of 10, being equal. The nature of the specific intensity, in the preceding sense, must be clearly understood to refer to that period of life only to which it is affixed, and not to be any index to the general value of life; for it will be seen that although male life possesses a higher specific intensity up to the age of 38, still female life is of a higher absolute value throughout the whole of the same period.

TABLE D exhibits the Expectation of Life as deduced from the data already described; and without attempting anything like an elaborate comparison between it and other tables, hitherto regarded as a near approximation to the real measure of life, such observations only will be made as appear to be more intimately connected with the subject of this paper.

It is clear that a table formed from the data at present under consideration, will shew the value of life in the country generally; all classes of society, from the highest to the lowest, being included; and it will therefore serve as a useful standard of comparison with the measure of life in individual classes of society, provided the rate of mortality in those classes can be determined.

In order to convey a general idea of the value of life as represented by TABLE D, it may be stated that it gives a greater expectation to males throughout the whole range of the table, than is given in the Table at page XIX. of the 5th Report of the Registrar General:

|                             |    |     |     |                |     |
|-----------------------------|----|-----|-----|----------------|-----|
| At Age 10 the difference is |    |     |     | .68 of a year. |     |
| ...                         | 20 | ... | ... | .81            | ... |
| ...                         | 30 | ... | ... | .97            | ... |
| ...                         | 40 | ... | ... | .92            | ... |
| ...                         | 50 | ... | ... | .83            | ... |
| ...                         | 60 | ... | ... | 1.00           | ... |
| ...                         | 70 | ... | ... | .44            | ... |
| ...                         | 80 | ... | ... | .15            | ... |
| ...                         | 90 | ... | ... | .15            | ... |

In the Twelfth Annual Report of the Registrar-General he has given a new Life Table, designated by him No. 2, the basis of which, in common with that in his Fifth Report, is the population of 1841, but the Mortality extends over the seven years, 1838-44. The results of this Table differ but little from the above.

[The value

TABLE D.

EXPECTATION—ENGLAND AND WALES—*Whole Population.*

| Age. | Males.  | Females. | Age. | Males.  | Females. |
|------|---------|----------|------|---------|----------|
| 10   | 47.7564 | 48.3826  | 59   | 15.1806 | 16.1552  |
| 11   | 47.1332 | 47.7648  | 60   | 14.5854 | 15.5320  |

| 33   | 32.1337 | 33.2541  | 82   | 4.6253  | 5.0031   |
| 34   | 31.4736 | 32.6149  | 83   | 4.3567  | 4.7109   |
| 35   | 30.8120 | 31.9750  | 84   | 4.1025  | 4.4351   |
| 36   | 30.1469 | 31.3312  | 85   | 3.8610  | 4.1726   |
| 37   | 29.4808 | 30.6867  | 86   | 3.6349  | 3.9258   |
| 38   | 28.8130 | 30.0390  | 87   | 3.4212  | 3.6938   |
| 39   | 28.1443 | 29.3877  | 88   | 3.2350  | 3.4781   |
| 40   | 27.4760 | 28.7330  | 89   | 3.0567  | 3.2778   |
| 41   | 26.8065 | 28.0742  | 90   | 2.8930  | 3.0944   |
| 42   | 26.1382 | 27.4125  | 91   | 2.7458  | 2.9256   |
| 43   | 25.4701 | 26.7479  | 92   | 2.6143  | 2.7703   |
| 44   | 24.8039 | 26.0809  | 93   | 2.4986  | 2.6276   |
| 45   | 24.1390 | 25.4120  | 94   | 2.3976  | 2.4950   |
| 46   | 23.4767 | 24.7420  | 95   | 2.3208  | 2.3750   |
| 47   | 22.8156 | 24.0703  | 96   | 2.2727  | 2.2632   |
| 48   | 22.1567 | 23.3985  | 97   | 2.1879  | 2.1587   |
| 49   | 21.4996 | 22.7263  | 98   | 2.1631  | 2.0644   |
| 50   | 20.8463 | 22.0545  | 99   | 2.1379  | 1.9757   |
| 51   | 20.1947 | 21.3834  | 100  | 2.1388  | 1.8750   |
| 52   | 19.5478 | 20.7137  | 101  | 2.0652  | 1.7564   |
| 53   | 18.9050 | 20.5461  | 102  | 2.0715  | 1.6304   |
| 54   | 18.2682 | 19.3821  | 103  | 1.9445  | 1.5000   |
| 55   | 17.6370 | 18.7220  | 104  | 1.6667  | 1.3571   |
| 56   | 17.0128 | 18.0682  | 105  | 1.2500  | 1.0000   |
| 57   | 16.3946 | 17.4236  | 106  | 1.0000  | .5000    |
| 58   | 15.7842 | 16.7865  | 107  | .5000   |          |

The value of Female Life, TABLE D, is also higher than Female Life in the Table of the Registrar General; the difference of Expectation in the two Tables being—

At Age 10 the difference is .57 of a year.

|     |    |     |      |     |
|-----|----|-----|------|-----|
| ... | 20 | ... | .79  | ... |
| ... | 30 | ... | .92  | ... |
| ... | 40 | ... | 1.01 | ... |
| ... | 50 | ... | .98  | ... |
| ... | 60 | ... | 1.12 | ... |
| ... | 70 | ... | .81  | ... |
| ... | 80 | ... | .44  | ... |
| ... | 90 | ... | .32  | ... |

A comparison of the expectation of Male Life in TABLE D with the Carlisle Table, which includes both sexes, will shew a higher value of life in the Carlisle Table up to age 54:

At Age 10 the difference is 1.06 of a year.

|     |    |                       |         |     |
|-----|----|-----------------------|---------|-----|
| ... | 20 | ...                   | .77     | ... |
| ... | 30 | ...                   | .24     | ... |
| ... | 40 | ...                   | .13     | ... |
| ... | 50 | ...                   | .26 and | ... |
| ... | 54 | they nearly coincide. |         |     |

Again, from that age up till 75 the difference is very little, but that generally against the Carlisle Table; and at 75 the Carlisle Table again crosses and maintains a superiority till the extreme of life.

The expectation of Female Life, as shewn in TABLE D, is higher than the expectation of the Carlisle Table after 15 years of age:

At Age 20 the difference being .14 of a year.

|     |    |     |      |     |
|-----|----|-----|------|-----|
| ... | 30 | ... | .83  | ... |
| ... | 40 | ... | 1.12 | ... |
| ... | 50 | ... | .94  | ... |
| ... | 60 | ... | 1.18 | ... |
| ... | 70 | ... | 1.66 | ... |
| ... | 80 | ... | .13  | ... |

... 88 they nearly coincide, and the Carlisle Table continues higher after that age.

A comparison of the mean of the expectation of Male and Female Life in TABLE D, with the expectation of the Carlisle Table, produces the following results, namely,

|             |                                                   |     |            |
|-------------|---------------------------------------------------|-----|------------|
| At Age 10   | the difference in favour of the Carlisle Table is | ·75 | of a year. |
| ... 20      | ... ..                                            | ·32 | ...        |
| ... 30      | the difference in favour of England & Wales is    | ·29 | ...        |
| ... 40      | ... ..                                            | ·49 | ...        |
| ... 50      | ... ..                                            | ·34 | ...        |
| ... 60      | ... ..                                            | ·71 | ...        |
| ... 70      | ... ..                                            | ·35 | ...        |
| Again at 80 | the difference in favour of the Carlisle Table is | ·09 | ...        |
| ... 90      | ... ..                                            | ·29 | ...        |

So that the absolute difference throughout the whole course of both Tables is very small, and the near approximation rather remarkable, considering the very different sources from which the data are derived. For a more minute comparison of those results with several of the best recognised Life Tables, reference is made to the Table in the Appendix, Note I.

Much attention has of late been given to the supposed influence of locality on the duration of life; still no public means have yet been employed to correctly solve the question. For the progress of vital statistics it unfortunately happens, that the public records of this country are kept with very little regard to method or unity of plan. The Report of the Census may certainly in itself be regarded as a very complete document; and perhaps no other country possesses such excellent Mortuary Registers; yet for almost every purpose of exact calculation, both documents are nearly useless. No two things should have been more intimately related in design and classification, than the Census of the People and the Registration of Deaths. Still they seem to have been compiled without any regard to each other. For example, if it were required to compare any two counties in England—a manufacturing with an agricultural county—an inland with a coasting county—in order to determine the relative value of life in the respective populations, it cannot at the present time be done. The Report of the Census Commissioners gives the population for those counties; but on reference to the reports of the Registrar General it is found that the deaths are given for quite a different arrangement of districts. Again, if it be required to compare one district of the Registrar General with another, the same kind of difficulty arises; for, on turning to the Census Report, those districts are in no way recognised. Precisely the same want in unity of plan is to be regretted in respect to the town districts of England, the districts of Census Commissioners constantly differing from those adopted by the Registrar General.

Were these difficulties overcome, it would then be easy to determine the difference of mortality in various districts, in precisely the same manner that the difference of mortality in male and female life has been found in the preceding Table. Another inquiry at least would however still remain, before it could be decided to what extent the difference of mortality was owing to the simple influence or peculiarity of locality itself.

At present it is right to assume, that either employment or occupation—condition in

life, or rank in society—poverty or riches—has as direct an influence on the duration of life, as peculiarity of locality or habitation; for the effect of neither one nor the other of the presumed influencing causes has yet been correctly defined. The truth of this assumption may appear more evident thus:—Suppose that the town of Liverpool were compared with some purely agricultural district, and that a much higher rate of mortality was found to prevail in the former; it would be no more right to assign this result wholly, or indeed any given portion of it, to the badly-conditioned streets and ill-planned houses of Liverpool, than to any other of the supposed causes.

In order to determine the simple influence of locality, like classes in the respective districts must be compared. In a comparison of districts A and B, if it so happened that in A two elements *c* and *d* were found to influence the value of life, while in B one only of those elements existed, the grounds of comparison would evidently be fallacious. Now this is precisely a parallel case to the state of things which exists in comparisons that have frequently been made between the manufacturing towns and the rural districts of England, and between one manufacturing town and another. Causes influencing the duration of life, independent of locality itself, frequently exist in the one, and not in the other; by overlooking which, observers are often led to assign excessive mortality to imaginary causes. If simple elements were compared, errors of this kind would be avoided. Keeping this in view, and referring to the preceding case, let *c* be supposed to represent comfort, and *d* distress. If, comparing comfort in district A with comfort in district B, a greater mortality were found to prevail in the former than in the latter, it would then be right to assume that the remaining elements—ill-ventilated houses, badly-drained streets, and the like—in district A, were not so favourable to life as in district B; but it would have been wrong to draw such a conclusion, had Comfort and Distress in the one district been compared with Comfort only in the other.

It is evident that, in a comparison of the general mortality of any one place with that of another, such errors could not be avoided. It may happen that the prevalence of a particular kind of employment or occupation in the one, which is not common to the other district—but which employment is of an unhealthy nature, or perhaps subject to great fluctuations in prosperity, or probably both combined—may produce an excessive mortality, the cause of which may be attributed to badly-planned dwellings, instead of to poverty and its train of direful consequences.

If it were possible to compare any one class in a given district with the same class under exactly similar circumstances in another district, the only distinction being the difference of district or locality, then it is plain that the influence of locality, if any, would manifest itself.

Again, if different classes of persons in the same locality were compared—for example, those following different employments—the only distinction being difference of employment, then the force of that element, if any, on the duration of life would appear.

In the present paper it is proposed to enter into this question, and to shew if possible

the influence of locality in the manner just described. The effect of employment on health will be treated of, on the present occasion, so far only as may be necessary to solve the question of locality.

About the time of the first edition of this paper going to press, the following correspondence took place with the Registrar-General on a kindred subject to that of the preceding seven paragraphs:—

GENERAL REGISTER OFFICE,  
26th February, 1845.

SIR,

I fear you may think that I am taking a great liberty in thus intruding upon you; but I hope that you will excuse the trouble I am giving you, when you consider that it is for a public object of very considerable importance.

It has been lately suggested to Her Majesty's Government, that more extended abstracts should be annually laid before Parliament relative to the births, deaths, and marriages registered in accordance with 6th and 7th William IV., c. 86; and I have received instructions to make a Report upon the subject to the Secretary of State for the Home Department.

My object in now troubling you, is to request you to turn your attention to this subject, and to favour me with any suggestions that may occur to you with a view to improvement, feeling assured, from your intimate acquaintance with these matters, that I shall not fail to derive assistance from the recommendations with which you may be pleased to favour me.

For the forms in which the particulars are recorded of each birth, death, and marriage, I beg to refer you to Schedules A, B, and C, in the Act of Parliament above alluded to; and in my Fourth, Fifth, and Sixth Annual Reports will be found the abstracts hitherto made and presented to Parliament.

I want information as to the improvements of which the abstracts are, in your opinion, susceptible, as framed from the entries in the Register Books now established by law, in combination with the returns of the population published in the Reports of the Census' Commissioners; and I wish to know what improvements, without involving any very large additional expenditure, you recommend for immediate adoption, as most urgently required.

I will not upon this occasion ask for your aid and advice with respect to alterations, which you may, perhaps, be disposed to recommend, regarding the forms in which the particulars in the original entries should be registered; nor with respect to original alterations which you may consider it advisable to introduce into any future Act of Parliament amending the present Registration Act; nor will I now allude to improvements which you may suggest relative to the particulars which it may be desirable to record in the next census of 1851,—if you will permit me to do so, I will, in another communication, advert to that subject. At present, I wish for your opinion as to the abstracts which it is most important should be annually given to the public, framed from the returns as at present made.

I have the honour to be, SIR,

Your faithful Servant,

F. G. P. NEISON, Esq.,

Medical, &c. Assurance Office,  
25, Pall Mall.

GEORGE GRAHAM,

Registrar-General.

25, PALL MALL,  
22nd March, 1845.

SIR,

In reply to your letter of the 26th ultimo, I beg to suggest a few alterations, which appear to me calculated to improve your Annual Reports as documents of public utility and importance.

In the registration of the "Causes of Death," an improvement would be effected by giving the age at death under each particular disease. This has already been done, to a limited extent, in your Third and Fourth Reports. To determine the value of life in various parts of the county, or in the country generally, it is essential to ascertain the ages at death, and when the progress or extent of any disease is inquired into, it is equally necessary to know the particular terms of life affected by that disease. In some parts of the country, Devon, Suffolk and Norfolk, for example, the population above 60 years of age is about 9 per cent. of the whole; but in Liverpool, Manchester, and Sheffield, the population alive above the same age is about 4.5 per cent., or one-half of the other;—it is therefore plain that apoplexy, or other diseases peculiar to old age, should have a higher ratio to the whole deaths in the former than in the latter, and this would be so, although the ratio of deaths in this disease to the population at given ages were the same; but at the present moment the Medical Inquirer cannot satisfy himself on this point, as the ages at death are not given.

Again, in the district of St. George's, Hanover Square, 36 per cent. of the population is between 15 and 30 years of age; but in Bethnal Green, 26 per cent. only is alive between those ages;—it is therefore evident that the deaths from consumption and other diseases prevalent at that term of life should also be in the same ratio, but if found in a different ratio there should be some means to account for the greater prevalence of the disease in one place than the other; however, as the ages under the head "Cause of Death" are not specified, it is at present impossible to carry out such an inquiry.

It will also be found that, between the ages of 20—40, the ratio of the population in the Metropolis to its whole population exceeds that of the County of Hereford by 32 per cent.; and provided that the ratio of the married population and of births were the same in both districts, the still births and deaths in childbirth should also shew an excess of 32 per cent. on the whole population. For all exact inquiries into the sanitary condition of various districts, as well as for the purposes of Medical science, the proposed change is highly important. It is not enough for Medical Statistics to know that a certain number of deaths has taken place from any given disease, the ages at death must also be known, and it will then be seen at what periods of life particular diseases are most destructive. A clear exhibition of the facts under this aspect would point out the fluctuations and progress of disease, and afford means of applying effective remedial measures. These remarks apply with particular force to the prevalence of epidemics. A reference to the Mortality Bills of Glasgow will shew that within the last 10 years the mortality in mature life in one year has sometimes differed by 125 per cent. from that of another. The advantage of being able to point out the particular diseases producing this most remarkable distinction at given terms of life is evident. So also in England and Wales would the same kind of information be valuable; in fact, unless the ages at death be given, I can see no important use to be made of the simple registrations of the total deaths under a given disease.

There is another improvement coming within the scope of the Registration Act that would be of great advantage in determining the sanitary condition of various districts, and which would at the same time furnish an important element in the remedial Medical measures already alluded to. That is, to specify the particular employment, as well as the "cause of death;"—to Medical science the advantage of this

information is obvious. The age and cause of death viewed in connection with the peculiarity of employment would often lead to important results; and it may be easily shewn that no satisfactory conclusion can be arrived at, in inquiries into the state of the public health, unless the influence of employment be taken into consideration. I have found by an investigation, the results of which are now in the press with a view to publication, that the mortality of some trades at particular ages is from 30 to 40 per cent. above that of others, and it is therefore evident that if any particular town or locality had a preponderance of the unhealthy trades to the exclusion of the more healthy, such circumstance would account for an increased rate of mortality, independent of any peculiar local influence on the duration of life. The alterations suggested would, in this respect, be highly advantageous to the country in affording the means to determine the causes of the increased mortality of various districts, and lead to the removal of the particular conditions which render some trades so much more fatal to life than others.

There is but one other change of any importance which I shall venture to suggest, and that will complete the principal combinations which Schedule B., in the Registration Act, admits of. When the deaths are given for each month, or other division of time, during the year, not only the sex, as in all other cases, but also the age, employment or trade, and cause of death, should be specified for that period of time. This to some may seem of secondary value, but a reference to your own Reports will be a sufficient reply. If the gross number of deaths, in any particular period or season of the year, be given, as at present, in order to determine the influence of climate on the public health, that question is not half answered unless it be also known at what ages the destruction of life has taken place, and what diseases have been the more immediate cause of death.

It appears to me, that with less information than would be given by the improvements suggested, little practical advantage can result from the Registration Act. These improvements are also quite within the spirit, in fact, in the direct terms, of the Act. Place, date, sex, age, employment, and cause of death, are the six facts required, under Schedule B., to be registered of every death, and I have often regretted that the Country had not all the advantages which the Registration Act thus seems intended to convey, and which would be given by a proper exposition of those six facts.

Any minor combinations or arrangements, that might be of interest or public utility, it is unnecessary to allude to, deeming it of primary importance to have all the elementary facts, in the first place, abstracted, leaving to individual inquirers complicated combinations, when the means to satisfy more immediate and important questions are provided.

I do not think it necessary to say anything in respect of Schedules A. and C. The collateral arrangements which should follow the changes now suggested in Schedule B. will be easily affected.

From your letter it does not clearly appear whether I should suggest anything in reference to the enumeration of the population. In your own Reports, the necessity which exists to ascertain the population, at each time of life, in any district, before any useful results can be derived from the registration of deaths, has been clearly illustrated. I therefore think it not out of place to state that, among those giving attention to Vital Statistics, I have repeatedly heard it much complained of that the Report of the Census Commissioners, and your own Reports, should have been compiled with so little regard to each other. It appears to me that no two things should have been more intimately related in design and classification.

If, at this moment, it were required to determine the comparative value of life in any two counties in England, or any two towns in England, there exists no means of accomplishing it. For if the population of any particular place is obtained from the Report of the Census Commissioners,

the deaths, in your own Report, will be found for quite a different arrangement of districts, and *vice versa*. It would, therefore, be of great public value if means were adopted to remedy this evil, and to render the districts, in some way or other, *coterminous*, or at least to obtain the enumeration of the population, at each term of life, in your own districts, for the period of the last census, and to arrange for the same being done at the next census in 1851. The reasons that have been given for the necessity of distinguishing the age at death do equally apply to the enumeration of the population. If the gross population, without distinction of age, were therefore given for each of your districts, that would not answer the purposes contemplated.

The sanitary condition of various districts engages, at the present time, much of the public attention, and it is important that your Reports should afford the means of testing the opinions which many individual inquirers have so readily advanced on limited data and insufficient evidence.

I have the honour to be,

SIR,

Your most obedient Servant,

F. G. P. NEISON.

To THE REGISTRAR-GENERAL.

---

It will be found, on referring to the census of 1851, that the improvements suggested have been to a great extent carried out, and, with great judgment, the responsibility of so difficult and arduous an undertaking was entrusted to the Registrar-General and his two eminent and distinguished assistants, Dr. Farr and Mr. Horace Mann. The result of their labours is the most complete and valuable census ever known in this or any other country. It is, however, to be regretted that the occupations of the population with distinction of age for quinquennial periods has not been given in the published Reports for smaller communities than "Registration Counties." The population was so abstracted as to shew the occupations of males and females at quinquennial ages in each of the 624 districts of the country, and the sheets are preserved for future use and reference: the publication of the tables would have involved so large an amount of printing that it was not thought right to increase the bulk of the census' publications, which in their present compressed form, extend over four large closely printed folio volumes.

For the solution of many of the questions alluded to in the preceding letter, "Registration Counties" are too often so extensive, and contain a population of so diversified occupations, as to render the information as now given of but little value in its application to minor districts included within the major division. For example, the West Riding of Yorkshire, containing a population of 1,340,051, includes the important towns of Leeds, Sheffield, Bradford, Halifax, Huddersfield, and Wakefield, with populations varying from 172,270 in the former to 22,057 in the latter; and the East Riding of the same County, having a population of 254,352, includes the Borough of Hull and the City of York—the former with a population of 84,690, the latter with a population of 36,303—two places very dissimilar in the occupations of the inhabitants. In like manner, Lancashire, with a population of 2,067,301, includes Manchester and Salford with a population of 401,321

and Liverpool with a population of 375,955—the former containing 48,344 persons recorded as engaged in “cotton manufacture,” and the latter only 1048; so also will it be found that the number described as “seamen, pilots, and others connected with sea navigation,” is 17,898 in the latter, and no more than 163 in the former. It is hence obvious that the distinction of ages, as given for quinquennial terms of life in connection with the occupations of the people for the “Registration Counties,” cannot be available for such smaller districts as those just pointed out. This is very much to be lamented, for it is to the great commercial and manufacturing places that the uses above all others of such improvements in the enumeration of the population are particularly applicable and important. At the same time it may be remarked that, as in the census of 1841, the ages were not distinguished for the different occupations; and as the schedules of that enumeration were not re-abstracted by those entrusted with the recent census to admit a comparison of their results with those of 1851, the figures distinguishing the ages of those engaged in different occupations at the latter date will be of little use until the period of next census, when it is to be hoped that the Commissioners then to be appointed will, notwithstanding the additional expense and increased bulk of publication, be enabled to give the country the same kind of information now furnished in respect to “Registration Counties,” not only for the “Registration Districts,” but for the “Sub-Districts” also. The records preserved in connection with the census of 1851 are not, in their present unpublished condition, available to the public, and seeing the country has already incurred the expense of analysing the various Schedules, the additional cost of printing should not prevent the results from being placed at the disposal of every inquirer into questions which are so important to the national interest.

In regard to the suggestions made in the preceding letter on the subject of the registration of deaths, those familiar with the Reports of the Registrar-General will be aware that they are year after year being gradually carried out, and that the mortuary records of England and Wales are even at the present time by far the most complete, precise, and important in the world.

On the appearance of the Registrar's next Annual Report it will be found to distinguish for several districts of the country the ages at death, the immediate causes, and the occupations followed by the different persons. If such should be done for each District, and if possible for each sub-District also, for every year from the date of last census until the next in 1861, and the improvements in the census itself likewise persevered in, the country will then be put in possession of a body of information of the utmost value, more correct and definite views cannot fail to be disclosed on the nature and extent of the causes which affect the sanitary conditions of great masses of our population, the health and longevity of the people must be speedily improved, and consequently the prosperity, happiness, and moral elevation of all classes advanced and promoted.

---

## DURATION OF LIFE IN VARIOUS CLASSES.

---

THE data to which this part of the inquiry belongs have been derived from two sources. One portion—that relating to the Friendly Societies in England—has been obtained through the kindness of Mr. J. Tidd Pratt; and consists of the Quinquennial Returns for 1836–1840, made under the Friendly Societies Act, 10 Geo. IV. c. 56. § 34, as amended by 4 & 5 Wm. IV. c. 40. § 6. And an inspection of the form of schedule given under that Act will shew the nature and extent of the information which can be derived from this source.

It was considered that Returns from the Friendly Societies in Scotland would form a valuable contribution to Vital Statistics, and at the same time be interesting to compare with the results obtained from English Societies; especially as Mr. Ansell's valuable work had given rise to many curious conjectures on the comparative amount of Sickness in the two countries; the inquiry made by the Highland Society having exhibited a less degree of sickness among the Scotch Societies, than the results of Mr. Ansell's investigation shewed to be prevalent in Societies in England. Accordingly, in 1840, a number of blank schedules were sent to nearly every parish minister in Scotland, with a note requesting him to use his influence with the neighbouring Friendly Societies, to induce them to furnish the information required; but the attempt to procure data in this manner proved an almost complete failure. In 1843 another attempt was made, but on this occasion prizes were offered to those making the best and most complete returns; which had the desired effect of procuring a series of schedules filled up evidently with much care; and although very elaborate, the nicest attention seemed to be given to the minutest detail. These constitute the second source from which the data just referred to are derived.

On the various Schedules on which the elementary facts of the inquiry were written being procured from the different Societies, they were, in order to award the prizes, submitted to the individual scrutiny of Mr. Farr, of the Registrar-General's Office; Mr. Fletcher, Honorary Secretary to the Statistical Society; Dr. Guy, of King's College; and Mr. Phillips, of the Westminster Hospital.

Every Schedule to which the least suspicion attached, or on which any of the elementary facts were deficient, were immediately rejected, and nothing but the most satisfactory records were admitted as a portion of the general data.

As it is proposed to enter into a few points only of the inquiry, in this paper, a form of the Schedule is given, that an idea may be formed of the extent of the information obtained, as well as the combinations of which the varied character of the data is susceptible.

## DURATION OF LIFE

Society, Established in the Year \_\_\_\_\_ in the Town of \_\_\_\_\_ County of \_\_\_\_\_

| MEMBERS. |                      | Date of Birth. | Date of Admission into the Society. | Age at the time of Admission. | Date of becoming a Free Member. | The whole amount of time to which the Member has been entitled to Aliment, including Bed-lying, Walking-about, and every other description of Aliment: during the Years— |       |        |       |        |       |        |       | The part of that time which he has been entitled to Walking-about Pay only: during the Years— |       |        |       |        |       |        |       | DEATH.  |        |                     |                           |  | Date at which the Member ceased to belong to the Society: whether from arrears of Contributions, from Expulsion, or from any other cause except Death. | Number of Attacks of Illness. | Remarks. |

| Name.    | Occupation or Trade. |                |                                     |                               |                                 | 1831                                                                                                                                                                     |       | &c.    |       | &c.    |       | 1842   |       | 1831                                                                                          |       | &c.    |       | &c.    |       | 1842   |       | Date of | Age at | Disease or Cause of | Period sick before Death. |  |                                                                                                                                                        |                               |          |
|          |                      |                |                                     |                               |                                 | Weeks.                                                                                                                                                                   | Days. | Weeks. | Days. | Weeks. | Days. | Weeks. | Days. | Weeks.                                                                                        | Days. | Weeks. | Days. | Weeks. | Days. | Weeks. | Days. |         |        |                     |                           |  |                                                                                                                                                        |                               |          |
|          |                      |                |                                     |                               |                                 |                                                                                                                                                                          |       |        |       |        |       |        |       |                                                                                               |       |        |       |        |       |        |       |         |        |                     |                           |  |                                                                                                                                                        |                               |          |
|          |                      |                |                                     |                               |                                 |                                                                                                                                                                          |       |        |       |        |       |        |       |                                                                                               |       |        |       |        |       |        |       |         |        |                     |                           |  |                                                                                                                                                        |                               |          |

1. When any particular case of Sickness may have commenced in one year, and continued to the following year, care must be taken to ascribe the proper quantity of Sickness to each year.
2. Every Member's name, or initials, must be entered in the Schedule, whether he may have received aliment at any time or not.
3. In filling up the columns of Sickness, Sundays are meant to be included. If it should be more convenient to exclude them, please to state that you have done so.
4. If the Member's correct date of birth, and also his age at admission into the Society, be known, it will be entered as such; if not, his present age, his age at death or at expulsion, as the case may be, must be guessed at or approximated to by the person who fills up the Schedule, and also by any other person who may know the Member in question, and inserted in the column headed "Remarks." The age on the preceding birthday should be taken, if not otherwise expressed.
5. If it be the practice of the Society to distinguish between Bed-lying and Walking-about Pay, care must be taken to fill up the respective columns.
6. The column of Deaths, as well as the column of Members who have been expelled, or who have left the Society, must be filled up with much care.
7. Should it be inconvenient or impossible to furnish the information for any particular column, or columns, it is hoped that the remaining ones will be filled up with as much accuracy as possible.
8. If it should happen that the information given respecting any particular Member stands in need of any explanation, such is to be given in the column headed "Remarks."
9. If the columns for the whole period of twelve years cannot be filled up, please to fill up as many as possible.
10. It will also be important to have an Abstract of the Society's Income and Expenditure filled up in the annexed Form.
11. A copy of the Society's Printed Rules or Regulations will be useful; and if such cannot be forwarded, then a written abstract of the terms of Contribution from Members, and of the benefits or aliments afforded them; with any other information of a useful nature relating to the Society.
12. A copy of the return of Sickness and Mortality sent to the Barrister or Advocate appointed to certify the Rules of Friendly Societies, would be very desirable.
13. Insert, in the column headed "Remarks," how many times the Member may have been sick during the period referred to in the adjoining columns; for example, a Member may have experienced, in any one or more years, twenty weeks of sickness, which may have been all one attack of illness or it may represent three or four different attacks of illness; and the number of attacks is to be stated, which can always be done by referring to the Society's books, and seeing the number of applications he has made for sick allowance.
14. It is also to be kept in view, that when a Member's death is recorded, it should be stated in the columns headed "Disease or Cause of," for what period he was ill in the attack of sickness immediately preceding his death.

*Abstract of the Society's Income and Expenditure.*

| Date of balancing in the respective years. |      | Amount of Income during the preceding year, from |                                      | Amount of Expenditure during the preceding year, on account of |                             | Amount of Stock in hand at each period of balancing. |
|--------------------------------------------|------|--------------------------------------------------|--------------------------------------|----------------------------------------------------------------|-----------------------------|------------------------------------------------------|
|                                            |      | Contributions not including Arrears.             | Interest of Stock and other Sources. | Aliment in Sickness.                                           | Funeral and other expenses. |                                                      |
|                                            | 1831 |                                                  |                                      |                                                                |                             |                                                      |

By this arrangement a means was afforded to measure the precise amount of Sickness and Mortality experienced by any particular Society, the ratio due to each year of life, and also how far its affairs were influenced by the particular trades and occupations of its Members.

All the Societies having been abstracted in this way, the results were afterwards combined in the following manner:—

The Societies belonging to the Rural Districts were placed in one group.

The Societies belonging to Town Districts were placed in another group.

And a third group was formed from those Societies established in the great Towns or Cities. A list of the places composing the respective groups of Rural Districts, Town Districts, and City Districts, is given in Appendix, Note II.

This plan was adopted in preference to a binary arrangement, in order to prevent a purely rural district from being mixed up with some of the smaller towns, and the great city districts with the larger towns.

The results of the first group, or Rural Districts, were then combined as follows. The totals of a given trade were placed on one of the Abstract Sheets; and the totals of the same trade in a second and a third Society, and so forth, were placed next in order on the same sheet, until all the Societies in the Rural Districts of the first county in alphabetical order were exhausted. The sums of those totals were then found, which shewed the amount of sickness and mortality among a certain number of persons at each age and of a given trade in that county. The same trade was carried through the rural districts of every other county in the same manner; and the totals for each county being added together, shewed the general result for that trade in the whole of the rural districts combined. The same trade was carried through the second group, or Town Districts, and also the third group, or City Districts, in precisely the same manner, so that an opportunity was thus afforded, of viewing the comparative degree of health, in the same occupation or employ-  
[ment,

## DURATION OF LIFE

TABLE E.

TRADES NOT CLASSIFIED.—RURAL DISTRICTS.—*Males.*

| Age. | Population.  |             | DEATHS.      |             |           | SICKNESS.    |             |            | Age. |

ment, in the three districts referred to. Those three districts were next combined, to give the general results for that trade without regard to locality. A second trade was taken up in the like manner, and carried through precisely the same steps, and so also were other trades until all were exhausted. The totals of the various trades in the Rural Districts were then combined, giving the general results for that district without regard to occupation, and so on with each of the other districts; and the combination of these last three gave of course the general results, without regard to either trade or locality.

All the possible combinations of those elements of the data being thus made, the next step was to exhibit the results in a convenient form, from which to make useful deductions. Tables were therefore formed, shewing the total number of persons, at every year of life over which the observations extend—the number of deaths among them yearly—and the amount of sickness yearly, expressed in weeks and decimals of a week. In the same Tables are also given the same facts for quinquennial periods of life, also the rate of mortality per cent., and the average amount of sickness per annum to each person.

As these observations extend over upwards of 400 different trades or occupations, the examination of each under the varied combinations described, would involve the consideration of so immense a number of Tables, as would evidently perplex the present inquiry. Such only will therefore be brought forward as seem to bear distinctly on the more immediate question, What is the influence of Locality on Health and on the Duration of Life?

TABLE E, one of the class just referred to, will be useful in pointing out the distinction in the rates of Mortality in quinquennial periods of life, between the Male Population in the Rural, Town and City Districts, and for minute purposes of detail will no doubt afford many interesting illustrations; but on the present occasion a more extended and general view of the results is necessary, and an inspection of Table F will therefore be of more importance. This Table is formed from Table E, in precisely the same manner that Table C was formed from Table B. On inspection of the results under the head “Rural Districts,” it will be seen that the highest Specific Intensity is attained at the youngest ages in the Table, and that it decreases up to Age 20, from which Age up to 31 it increases, and then decreases gradually till near the extreme of life. A comparison of the Specific Intensity as given in this Table, with the general result for the Male Population in England and Wales as set forth in Table C, will shew a higher intensity of life through the whole range of the Table, maintaining at the same time a very remarkable parallelism.

It will be seen that the Specific Intensity

At Age 20 in Table C is as high as at Age 39 in Table F (Rural Districts)

| 52   | 71369   | 1143   | 1·6011                 | 62·461                 | 98   | 214     | 113    | 52·9127                | 1·890                  |
| 53   | 70226   | 1191   | 1·6955                 | 58·997                 | 99   | 101     | 62     | 61·3067                | 1·631                  |
| 54   | 69035   | 1239   | 1·7947                 | 55·710                 | 100  | 39      | 39     | 75·0000                | 1·333                  |
| 55   | 67796   | 1287   | 1·8986                 | 52·659                 |      |         |        |                        |                        |

An approximating value taking place up to about this period, after which they again diverge to near the extreme of life.

The population existing at Age 10 in Table C is halved between ages 62-3; while in Table F (Rural Districts) the same result is not determined till ages 68-9;—shewing under this aspect a superior vitality of six years.

If the results in Table F for the Town Districts be now inspected, it will be seen that the Specific Intensity decreases in a regular series, from the beginning to the extreme of the Table. It will also appear that the Specific Intensity is higher than Male Life in Table C up to Age 52, and from that to age 76 it is less. From the latter age to the extreme of life, they cross each other. The following are the ages at which the corresponding Specific Intensities in Both Tables are nearly equal.

Age 20 in C corresponds with Age 31 in F (Town Districts)

|        |     |     |    |     |
|--------|-----|-----|----|-----|
| ... 30 | ... | ... | 41 | ... |
| ... 40 | ... | ... | 45 | ... |
| ... 50 | ... | ... | 50 | ... |
| ... 60 | ... | ... | 58 | ... |
| ... 70 | ... | ... | 68 | ... |
| ... 80 | ... | ... | 82 | ... |

In Table F (Town Districts) it will be seen that half the population disappears between ages 64-5, and it has been shewn that in Table C the same result takes place at ages 62-3.

Turning next to the results for the City Districts in Table F, it will be seen that the Specific Intensity decreases from the earliest age to the other extreme of the Table, in a uniform series. In this Table it will also appear, that from the age of 10 to 33 there is a higher Specific Intensity than in Table C; and from 33 to the extreme of life, the Specific Intensity in the City Districts of Table F is less than in the Male Life of Table C, which represents the general results for England and Wales. The following will shew the ages corresponding to equal specific intensities in both Tables:—

Age 20 in C corresponds nearly with age 25 in F (City Districts)

|        |     |     |    |     |
|--------|-----|-----|----|-----|
| ... 30 | ... | ... | 33 | ... |
| ... 40 | ... | ... | 37 | ... |
| ... 50 | ... | ... | 46 | ... |
| ... 60 | ... | ... | 59 | ... |
| ... 70 | ... | ... | 69 | ... |
| ... 80 | ... | ... | 79 | ... |

Half of the population, it will be seen in Table F (City Districts), has died off between the

ages of 61 and 62, while among Males in England and Wales that happened at ages 62 and 63; being in this instance one year in favour of the Table for the General Results of the Country.

Taking a view of the three Districts respectively, as given in Table F, in conjunction with Table C, it will be seen that there is

A higher Specific Intensity in the Rural Districts up to the extreme of Life, than in Table C,

|     |     |                                    |     |     |     |     |
|-----|-----|------------------------------------|-----|-----|-----|-----|
| ... | ... | Town Districts up to the Age of 52 |     |     |     | ... |
| ... | ... | City                               | ... | ... | ... | 33  |

From this it would appear, that the lower the age of equal Specific Intensity, the worse the class of lives to which it refers. Another comparison of these three classes of results with Table C will shew the following series of Differences for the corresponding ages of equal Specific Intensity:—

| Age.                              | Rural Districts. | Town Districts. | City Districts. |
|-----------------------------------|------------------|-----------------|-----------------|
| 20                                | 19               | 11              | 5               |
| 30                                | 17               | 11              | 3               |
| 40                                | 10               | 5               | 3               |
| 50                                | 5                | 0               | — 4             |
| 60                                | 3                | — 2             | — 1             |
| 70                                | 1                | — 2             | — 1             |
|                                   | —                | —               | —               |
| Sums of the series of differences | 55               | 23              | 5               |

This arrangement of the differences of corresponding periods of equal Specific Intensity also points out a gradual approximation to lower numbers, moving from the Rural towards the City Districts. And a third illustration of the same fact will be found in comparing the periods at which the equation of life is determined for age 10. It is in—

| Table C.     | F—Rural Districts. | F—Town Districts. | F—City Districts. |
|--------------|--------------------|-------------------|-------------------|
| At Ages 62—3 | 68—9               | 64—5              | 61—2              |
| difference   | 6 years.           | 2 years.          | — 1 year.         |

As before stated, the illustrations drawn from the Specific Intensity must be understood to have reference to the identical periods only of life at which the comparisons are made, and not to the absolute value of life in any of the classes. It will, however, at all times, be found important to keep in view the specific intensity of such Tables, as it affords the readiest means to discover those periods at which any peculiar change or difference in the condition of life is taking place. Various diseases have a maximum or minimum effect in destroying life at certain periods; and if a change to a higher specific intensity were found to take place at any given period, the diseases peculiar to that period should be falling from their maximum towards the minimum.

In the three Districts now under consideration, it appears that in all except one, the Specific Intensity uniformly decreased from the beginning to the end of the Table; but in the Rural Districts the Specific Intensity was found to increase from ages 20–31. Some change, either in the Rural Districts, or uniformly in the two others, must therefore have taken place in the causes affecting the duration of life at that period; and if the nature of this paper led to an examination of the diseases generally prevalent at the same period, the probability is that Consumption and Diseases of the Chest would be found less malignant at that term of life, in relation to the preceding and subsequent periods of life, in the Rural than in either the Town or City Districts.

The next arrangement of the data to which reference will be made, is the “After-lifetime,” or Expectation of Life. This mode of expressing the Duration of Life is certainly that which is of the most interest to society; for it points out the average number of years which one member of the community with another participates in the pleasures and cares of life. The Expectation of Life is often confounded with the chance of living an equivalent number of years; but the distinction will be subsequently explained.

In Table G will be found the Expectation of Life for each of the three districts, and also the General Results for those three combined. A comparison of the expectation under the head “Rural Districts,” with the expectation for Males in England and Wales, as given in Table D, will shew a much higher value of life in the Rural Districts throughout the whole range of the Table. At age 10 the difference is 5·5 years in favour of the Rural Districts, at 30 it is 4·3 years, and at 60 the difference is 2·1 years. The following arrangement of the results of the two tables, at decennial periods, will convey a general idea of their relative values of life:—

| Age. | EXPECTATION.     |                    | Difference in favour of the Rural Districts. |           |
|------|------------------|--------------------|----------------------------------------------|-----------|
|      | Rural Districts. | England and Wales. | In Years.                                    | Per Cent. |
| 20   | 45·3550          | 40·6910            | 4·6640                                       | 11·462    |
| 30   | 38·4073          | 34·0990            | 4·3083                                       | 11·191    |
| 40   | 30·9724          | 27·4760            | 3·4964                                       | 12·725    |
| 50   | 23·4700          | 20·8463            | 2·6237                                       | 12·585    |
| 60   | 16·6524          | 14·5854            | 2·0670                                       | 14·171    |
| 70   | 10·9124          | 9·2176             | 1·6948                                       | 18·386    |

A comparison of the results for the Town Districts, will shew a superior expectation up to Age 35, after which period the expectation is in favour of Male Life, in the General Table for England and Wales. The following Abstract shews the results for decennial periods.

[The Expectation

TABLE G.

EXPECTATION.—TRADES NOT CLASSIFIED.—*Males.*

| Age. | Rural Districts. | Town Districts. | City Districts. | Rural, Town, and City Districts. | Age. | Rural Districts. | Town Districts. | City Districts. | Rural, Town, and City Districts. |

The Expectation of Life in the City Districts will be found to be less than in Table D, from age 12 upwards. At 20 the difference is .68 years, at 40 it is 1.39 years, and at 60 the difference is .82 years in favour of the general value of Male Life in Table D. The following gives a comparative view of both Tables:—

| Age. | EXPECTATION.    |                    | Difference in favour of England and Wales. |           |
|------|-----------------|--------------------|--------------------------------------------|-----------|
|      | City Districts. | England and Wales. | In Years.                                  | Per Cent. |
| 20   | 40.0148         | 40.6910            | 0.6762                                     | 1.664     |
| 30   | 32.8603         | 34.0990            | 1.2387                                     | 3.632     |
| 40   | 26.0873         | 27.4760            | 1.3887                                     | 5.054     |
| 50   | 19.9271         | 20.8463            | 0.9192                                     | 4.409     |
| 60   | 13.7685         | 14.5854            | 0.8169                                     | 5.608     |
| 70   | 8.7636          | 9.2176             | 0.4550                                     | 4.092     |

The comparative value of life in the three districts at decennial periods will be seen by an inspection of the following Table; the 6th and 8th columns of which will point out the gradual decrease in the value of Life in moving from the Rural to the Town, and from the Town to the City Districts:—

| Age.              | EXPECTATION OF LIFE. |         |         | Excess in favour of Rural, over |           |                 |           |
|-------------------|----------------------|---------|---------|---------------------------------|-----------|-----------------|-----------|
|                   |                      |         |         | Town Districts.                 |           | City Districts. |           |
|                   | Rural.               | Town.   | City.   | In Years.                       | Per Cent. | In Years.       | Per Cent. |
| 20                | 45.3550              | 42.2742 | 40.0148 | 3.0808                          | 6.790     | 5.3402          | 11.774    |

| 40                | 30.9724              | 27.1530 | 26.0873 | 3.8194                          | 12.331    | 4.8851          | 15.772    |
| 50                | 23.4700              | 19.9733 | 19.9271 | 3.4967                          | 14.900    | 3.5429          | 15.100    |
| 60                | 16.6524              | 13.7608 | 13.7685 | 2.8916                          | 17.364    | 2.8837          | 17.318    |
| 70                | 10.7124              | 8.7030  | 8.7636  | 2.2094                          | 20.246    | 2.1488          | 19.691    |
| Total Excess..... |                      |         |         | 19.3299.....                    |           | 24.3479         |           |

The next arrangement of this kind which will be brought under notice is the Expectation of Life as derived from the combination of all the data composing the three Districts now referred to; and may be understood to represent the general value of Male Life as it exists among the Members of the Community composing Friendly

Societies. Throughout the whole range of this Table the Expectation of Life is found to be higher than among the male population of the country generally. A glance at the following abridgment of Table G, for the three Districts, will shew the difference at the given periods of life:—

| Age. | EXPECTATION IN   |                    | Difference in favour of the Three Districts. |           |
|------|------------------|--------------------|----------------------------------------------|-----------|
|      | Three Districts. | England and Wales. | In Years.                                    | Per Cent. |
| 20   | 43·7736          | 40·6910            | 3·0826                                       | 7·575     |
| 30   | 36·6051          | 34·0990            | 2·5061                                       | 7·349     |
| 40   | 29·3306          | 27·4760            | 1·8546                                       | 6·750     |
| 50   | 22·1920          | 20·8463            | 1·3457                                       | 6·455     |
| 60   | 15·6942          | 14·5854            | 1·1088                                       | 7·602     |
| 70   | 10·2057          | 9·2176             | 0·9881                                       | 10·720    |

A very important distinction is here found to prevail between the value of life in the two Tables. The circumstances in which the humble and working population of the country is placed, have generally been thought adverse to a prolonged duration of life; but the healthiest Life Tables hitherto formed have not shewn any thing so favourable as the present results, even among what are generally considered the select classes of Society:—

It may be well to be understood here, that the persons composing Friendly Societies are almost exclusively the hard-working members of the community, chiefly occupied in the drudgeries and toils of the mechanical arts, and consequently exposed to the inclemencies of seasons, excesses of temperature, impure atmospheres, constrained postures, and other conditions usually thought objectionable. Their incomes are very limited, affording but the scantiest and simplest means of support. Their habitations are of an inferior order, being of the cheapest kind, and consequently in the worst streets. The Members of Friendly Societies are therefore generally placed in those circumstances which persons habituated to the luxuries of the upper ranks of society would regard as unfavourable to health and a superior duration of life. In making these remarks, however, it is necessary, as will hereafter be seen, to make a distinction between them, and the great bulk of the poorer classes of the country. For an individual to remain a Member of a Friendly Society, it is required that he should make his weekly or monthly contribution to its funds; and although a few pence is all that is needed, it presumes on a certain amount of frugality and industrial habit, sufficient to separate him from the reckless and improvident, who are more openly exposed to the vicissitudes—poverty, distress, destitution and disease—incidental to fluctuations in the demand for labour.

The superior value of life among the Members of Friendly Societies is a very remarkable and important feature in this inquiry, and is a result that generally would not have

been anticipated ; and the question which naturally follows is, From what source or class does the excess of mortality, which makes up the general average of the community, arise ?

Those persons having transactions with the Assurance Companies belong, with a very few exceptions, either to the middle or the higher ranks of society ; and if the value of life, as deduced from observations in those Companies, be admitted as a correct measure for such classes, it will be found that their duration of life is not only less than among the Members of Friendly Societies, but also less than in the country generally.

In TABLE H. No. 5, col. 2nd, the Expectation of Life is given as deduced from the aggregate observations of Assurance Companies, and includes both sexes ; but col. 1st (Males *d* 1) of the same Table relates to Male Lives only, and is consequently that which should be brought into comparison with the results of this inquiry.

It may be said, in reply to some of the preceding observations, that the superior value of life in the ranks of Friendly Societies, above the general community, is owing to the effects of selection ; but a little reflection will shew that the difference must be produced by other causes. Every reasonable means is adopted to test the lives admitted into Assurance Companies, and yet they appear to be of less value than the general average of the country ; and Friendly Societies are known *not* to exercise the same degree of scrutiny. In both, the interest of the applicant for admission is opposed to that of the Society ; and, looking at the results, it is not unlikely that the vigilance of the one may be neutralised by the interests of the other. Another result brought out by the observations on the lives in Assurance Offices will shew how inadequate the means of selection usually resorted to are to raise the standard of life above the average of the country. All other inquiries hitherto made on Male and Female Life have tended to attach a greater value to the latter than to the former ; but the results in the Assurance Companies have been reversed, shewing that some other causes, beyond the method of selection, must have interfered to modify the state of health ; for if the means of scrutiny had been adequate to determine the actual character and condition of health, the prevailing feature of each sex would have manifested itself, and the anomalous results of Male Life being of higher absolute value than Female Life not appeared.

Assurance Companies, it has been stated, are likely to have proposals most freely from among unhealthy persons for sums payable at death ; but that proposals for annuities, or sums payable during life, will be made on the lives of the most healthy only ; and that the private opinion of the individual being always brought to bear against the Company, the effects of selection under this aspect ought to prevent the results of such observations from being regarded as a true exponent of the value of life in the class of society generally to which those persons belong. There exists no published document, so far as Assurance Offices are concerned, to shew whether this opinion is well founded : but there is evidence of the same kind—of equal, or perhaps, from its  
[greater

TABLE H.

greater extent, of higher value than any to be drawn from the Assurance Companies ; it happens, however, that assured lives are of greater instead of less value than those of annuitants. The tables calculated by Mr. Finlaison, on the lives among the nominees of the Government Tontines and Annuity schemes, are here alluded to. The facts over which his observations extended possessed almost every advantage that could be desired ; and, considering the acknowledged skill and care with which his computations were managed, the Government Table must be entitled to the highest confidence, and the Expectation of Life thence deduced regarded as the true measure of life in that particular class of society.

TABLE H, No. 6, has been recalculated for the present paper from the facts given by Mr. Finlaison at page 67 of his Report on Life Annuities in March 1829—being the combined results of six different classes of observations on male lives. That usually quoted as the Expectation Table of the Government Annuitants, is the one calculated by Mr. Finlaison in 1825, and differs in some important particulars from his subsequent and revised data in 1829. This table, then, will shew that the male lives selected for the Government Annuities are not only of less duration than the male population of the country generally, and are also of less value than lives in Assurance Companies, but are actually shorter lived than the members of Friendly Societies in the City Districts. It is evident from those results, that the presumed power of the individual to judge of his own state of health has not shewn the remarkable effects anticipated : there is more reason to believe that the natural inclination with which every person is led to look upon his life as good, will very much influence any power of discrimination on his own chances of longevity. It is, however, to be kept in view, that persons of decidedly bad health will rarely purchase annuities ; and the exclusion of these has, no doubt, some effect in slightly raising the standard of the table. A similar observation is also to be made with respect to the applicants to Assurance Companies. There is a strong temptation for those in really bad, or at least in indifferent health, to offer themselves for assurance ; and if all were admitted, no doubt a lower value would be expressed by the results in Table H, No. 5. The known caution, however, usually exercised in these matters, and the medical talent brought to the aid of the Offices, is a protection against the very worst lives of that class ; about 23 per cent. of the applicants being the average number rejected.

Friendly Societies, although not equally solicitous, are still not without tests for the admission of Members, and they possess one advantage over Assurance Companies ; the Members, and those likely to be candidates, are generally intimately known in their daily habits and ordinary health to each other ; and where evidently bad health exists, admission is refused. A consideration of all that has been advanced will shew that the greater vitality among Members of Friendly Societies cannot be accounted for by the superior mode in the selection of lives ; for, if that argument were carried out to its full extent,

it would go to prove that the other classes in question had, in that respect, the advantage. The blessing thus bestowed on the frugal and industrious workmen of the country composing Friendly Societies, in having granted them, as appears by the present inquiry, a prolonged duration of life, must therefore be regarded as a really true and distinctive feature of that class of persons, and is, no doubt, the result of their simple and uniform habits of life, and the more regular and natural physical exercises to which they are habituated.

If the nature of the present paper led to a further investigation of this point, it could be clearly shewn, by tracing the various classes of society in which there exists sufficient means of subsistence, beginning with the most humble, and passing on to the middle and upper classes, that a gradual deterioration in the duration of life takes place; and that just as life, with all its wealth, pomp, and magnificence, would seem to become more valuable and tempting, so are its opportunities and chances of enjoyment lessened. As far as the results of figures admit of judging, this condition would seem to flow directly from the luxurious and pampered style of living among the wealthier classes, whose artificial habits interfere with the nature and degree of those physical exercises which, in a simpler class of society, are accompanied with a long life.

Thus far, then, it is plain that the amount of life enjoyed by the middle and upper classes tends rather to depreciate than elevate the standard deduced from the general results of the country. And carrying this out still further, and viewing the value of life in the highest ranks of society—namely, the peerage and baronetage—as given in the recent and very interesting paper submitted by Dr. Guy, it will be seen that the Expectation of Life is not only less than in the general community, but also very much below the measure of life *among the Members of Friendly Societies in the CITY DISTRICTS*. The Expectation of Life in the peerage will be found in Table H, No. 3. It may then be conclusively admitted, that the standard of life in the general community is not elevated in any way by the influence of the middle or upper classes. With regard to the very highest ranks, the opposite conclusion must be come to; but as the numbers of the nobility are relatively small, the inferior value of life there shewn is not sufficient to account for the reduction of the scale for the general community so much below the average standard of all classes in Friendly Societies.

It hence follows that the excess of mortality in the general community must fall on the residue of the people; and although at present there exists no direct means of measuring the precise value of life in that portion of the population, it is evident that an inferential one of equal importance is immediately available.

Admitting that the preceding Tables form a correct representation of the value of life in the respective classes, it will be easy to arrive at the value of life in the remaining class; for—

Let Table A represent the rate of mortality in the general community—viz. over all England and Wales;

And let  $b$  = rate of mortality in one class—viz. Friendly Societies—and forming a part of A or included in it;—Also

Let  $c$  = rate of mortality in a second class—viz: the middle and upper classes, and also included in A;—then it is evident that

$A - (b + c)$  = the rate of mortality in the remaining class, composing the Community. And this latter class includes the improvident and reckless, the poor and the destitute, who are exposed to the inclemencies of the seasons, the fluctuations of trade, and fall victims to epidemical and other diseases. Subsequent illustrations will more clearly establish this fact, when the question of large towns or cities is brought under consideration.

In making the preceding comparisons of the mortality of the Rural, Town, and City Districts respectively, with the average results for the whole population of England and Wales, no further corrections of the figures than those described were needed; but before bringing the table representing the combined results of the three districts into comparison with the mortality of the whole population of the country, it would have been important to be enabled to apply a further correction to the elementary data.

An inspection of the arrangement of the data presented in Table E will shew, that if

R, T, and C, represent the population over which the observations in that Table extend, for the Rural, Town, and City Districts respectively and

$r$ ,  $t$ , and  $c$  represent the number of deaths in the same population for the respective districts at each period of life;

then the mortality per cent., and consequently all subsequent results for the average of the three districts, or rather the three districts combined, as set forth in Table E, is derived from—

$$\frac{(r + t + c) \cdot 100}{R + T + C}$$

This is the usual mode by which general averages for various classes of lives have been hitherto determined; but it is evident that unless R, T, and C, bear the same ratio to each other which the whole population of the districts they represent do to each other, the average results cannot be true.

This fact may be rendered more intelligible by the following hypothetical illustration. Suppose at any given age the population over which the actual observations extend was 100 for each of the three districts, viz:—

|              |         |               |       |
|--------------|---------|---------------|-------|
| For District | R = 100 | Annual Deaths | 2     |
| ...          | T = 100 | ...           | 3     |
| ...          | C = 100 | ...           | 4     |
|              | <hr/>   |               | <hr/> |
| R + T + C =  | 300     | ...           | 9     |

then the average result thus derived would shew a mortality of 3 per cent.; but if the whole population of those districts had been to each other in any other relation than an equality of numbers—say 100, 50, and 25—then the number of deaths would have become 2, 1.5, and 1, respectively: consequently, the correct average mortality would have been 2.571 per cent. instead of 3 per cent.

The following mode of obtaining a correct average has also been suggested, but it is obvious that it would involve errors of a more serious nature than the common method employed.

$$\frac{r \cdot 100}{R} + \frac{t \cdot 100}{T} + \frac{c \cdot 100}{C}$$

---

$$3$$

A single illustration will be adequate to point out the fallacies of this.

At age 40—45 the actual mortality of the Rural District is .8361 per cent:

|     |     |                |        |     |
|-----|-----|----------------|--------|-----|
| ... | ... | Town Districts | 1.0637 | ... |
| ... | ... | City Districts | 1.6084 | ... |

Average for the three 1.1694

But supposing the actual population of the whole of each district at that age was in the ratio of 82763, 34220 and 25428, which are the actual numbers in Table E at this term of life, then the correct average mortality of the whole kingdom would be 1.0287 per cent. but the above result was ... .. 1.1694

Difference 0.1407 or an

error on the amount of the true result of 13.7766 per cent.

Although TABLE E, for all the Districts combined, is a correct measure of the average mortality of Friendly Societies in England and Wales, being composed of the actual numbers in those Districts, and in this respect perfect for the purposes of Friendly Societies; yet, unless the numbers representing, at particular years of age, each of the three Districts in TABLE E, bear the same ratio to the combined Districts of that Table, at the same ages which the actual population of the country in each of these Districts has to the whole population of the country at those ages, corrections would be required for purposes of comparison with the general mortality of the kingdom. But for the same reasons that the corrections suggested would improve the Table for comparison with the general mortality of the country, would they also injure the results for the purpose of Friendly Societies. It would, therefore, be better to have the facts under both forms.

As stated in the early part of this paper, if the districts of the Census Commissioners and Registrar-General had been coincident or coterminous, the labour of determining the population at each term of life for the three corresponding Districts would have been well repaid.

As already stated, these observations do not in any way affect the Rates of Mortality as represented in any one District, but affect the combined results for the three Districts only. So far as any individual District is concerned, or the comparison of one District with another, or with the general mortality for the whole kingdom, those objections do not apply, for in respect of locality simple elements only enter into the data of each district.

To some it may appear that too much importance has been given to the nature of this error; but as it so constantly enters, under some aspect or other, into nearly all inquiries into Vital Statistics, frequently producing errors of considerable magnitude, it has been deemed necessary to allude to it at length.

The distinction between the Rates of Mortality in the three Districts has been already pointed out; and so far as a single expression of the value of life among those classes, in given Districts, is required, nothing more is needed; and the difference between the tables will shew the relative value of life in the given Districts. Hitherto it has been thought sufficient to rest at this stage in all inquiries into the influence of locality on the Duration of Life, and to assign the difference thus appearing in the value of life between the respective Districts to the peculiar influence of Town or City Life. Other causes than locality will, however, be shewn to influence the Duration of Life.

If the data composing the facts presented in the preceding Tables be analysed, so as to distinguish one employment from another, it will be found that some occupations are much more healthy than others. The first evidence of this to be brought forward will be confined to the Rural Districts. An inspection of TABLE I, which represents the Mortality of Labourers in the Rural Districts, chiefly agricultural labourers, will shew a much higher specific intensity to the age of 80 than the general results for all employments in the Rural Districts; the specific intensity of Labourers, however, decreases in a gradual and regular series from the youngest ages in the Table, following the rule of the general results of the other Districts, and not presenting the apparent anomaly of the general results for the Rural Districts by shewing an increasing specific intensity from twenty to thirty-one years of age. It will be found that the specific intensity of the General Results for the Rural Districts—

At Age 20 in TABLE F, is as high as age 41 for Labourers in TABLE I;

The Population in TABLE F was shewn to be bisected at ages 68-9, while among the Labourers that will be seen to take place at ages 71-2. The sum of the series of differences of the points of equal specific intensity between the Rural, Town, and City Districts respectively, and Table C, were shewn to be 55, 23, and 5; but the sum of the same order of differences for Table I is 78; so that the difference between Labourers and the General Results for the Rural Districts is more than equivalent to the mean difference between Towns and Cities and the Rural Districts. It will also be seen that the sum of the series of differences of the points of equal specific intensity in the Rural Districts generally, and the Labourers, is 46, being above the mean of 55 and 23.

The difference for the equation of life to

Age 10, between Rural and Town Districts, is 4 years.

...      ...      Town and City      ...      3      ...  
and      ...      Labourers and Rural      ...      3      ...

So that, in this general way of viewing the question, employment produces as wide a distinction as locality.

If TABLE J is now referred to, it will be seen that the Expectation of Life among Labourers in the Rural Districts exceeds the Expectation of the Rural Districts generally throughout the whole term of life. At decennial ages the following is the relative value of life.

| Age. | Rural Districts.       |                  | Difference in favour of Labourers. |           | Age. |
|------|------------------------|------------------|------------------------------------|-----------|------|
|      | General Results.<br>G. | Labourers.<br>J. | In Years.                          | Per Cent. |      |
| 20   | 45·3550                | 47·9063          | 2·5513                             | 5·6251    | 20   |
| 30   | 38·4073                | 40·5972          | 2·1899                             | 5·7017    | 30   |
| 40   | 30·9724                | 32·7693          | 1·7969                             | 5·8016    | 40   |
| 50   | 23·4700                | 25·0745          | 1·6045                             | 6·8500    | 50   |
| 60   | 16·6524                | 17·8205          | 1·1681                             | 7·8146    | 60   |
| 70   | 10·9124                | 11·3498          | 0·4374                             | 4·0072    | 70   |

The preceding arrangements, however, do not shew the full influence of employment on health, or rather that of an individual employment on health; for, in making comparisons of classes with any standard, that standard ought not to include the class held in comparison, but be the residue left by abstracting that class from the general results; otherwise the effect of that class, in changing the integral expression, will not be seen to its full extent, and the concealment of the real difference will be the greater in proportion to the

## DURATION OF LIFE

| 55   | 16.8251                                                    | 14.3131                                                  | 19.2764                                                          |      |                                                          |                                                          |                                                                  |

high ratio which the numbers of the class compared bear to the total number. For example :—

Let  $a = 20$  per cent. and represent the total results or general average; and  
 $\left. \begin{array}{l} \dots b = 25 \\ \dots c = 15 \end{array} \right\}$  per cent. and represent classes composing the general average  $a$ ;

then, if either class  $b$  or class  $c$  were compared with the total result or general average, the apparent difference would be only 5 per cent.; while the actual difference between it and the residue class is 10 per cent. Hence, if any class of results be compared with the general results in which that is also included, the apparent difference will always be less than the actual difference, whether the effect of that class be to increase or decrease the ratio of the general results.

The facts forming Table I, No. 1, have therefore been eliminated from the general results for the Rural Districts in Table E, and the residue formed into another Life Table, from which Table I, No. 6, has been deduced; and it will be found that the specific intensity for the Rural Districts generally is as high

at Age 20 in Table F Rural Districts as at Age 16 for the Residue.

| 70 | ... | ... | 72 |

Half the population dies off at Age 65–66 in the Residue, at Age 68–9 in the General Average, and at Age 71–2 in the Labourers.

The great distinction between the value of life among the labouring population in the Rural Districts, and the rest of the Rural Districts, is therefore obvious; and conclusively shews, that even in the same locality, in the Rural Districts of the country, where all the supposed contaminating influences of ill-ventilated houses, narrow streets, bad sewerage, poisoned air, epidemic town fevers, and factory restraints, are absent, there is nevertheless a very great superiority in the value of life in one class over another. In the

Rural Districts recited in the early part of this Paper, very little difference can be supposed to exist between the means of support and the various habits of life of the members of Friendly Societies. In fact, they may be presumed to assimilate as near to each other's condition as any means of classification can suggest, the only difference between the individual members being difference of employment or occupation; and therefore, in classifying the various trades, pure elements may be said to be brought into comparison, the only distinction being difference of occupation.

It has already been stated that any thing like a complete inquiry into the influence of employment on health is not contemplated in this Paper. A few illustrations only will be brought forward to aid the other branch of the inquiry, and by which it will be seen that, independently of locality, difference of employment has a marked effect on the duration of life.

If this position can be fairly established, it will follow as a direct consequence, that wherever an excess of unhealthy trades are congregated, there must also be an increased rate of mortality independent of the local influence; for if the same trades were placed in any other district, there would still be an increased rate of mortality simply in virtue of the trade or occupation.

At Ages 30-35, the general mortality of the Town Districts exceeds that of the Rural by 14.981 per cent. of the whole mortality at that period of life; but if the class designated Labourers were abstracted from the Rural District, the mortality of the residue would be increased 6.181 per cent. of the original ratio. But suppose a still further change to take place, and that the class named Labourers is not only abstracted from the Rural Districts, but added to the Town Districts; this arrangement would affect the respective mortalities to such an extent, that instead of the mortality of the Town Districts exceeding that of the Rural Districts by 14.981 per cent., it would fall short of it by 1.831 per cent. of the whole mortality at that period of life. In like manner also would other periods of life be affected. It is evident, therefore, that the Residue of the population in the Rural Districts has a factitious value assigned to it, from being mixed up with the class called Labourers; and that in any attempt to discover the relative values of life in different localities, unless employment were made an element in the comparison, an undue value would be attached to a great portion of life in the Rural Districts. The nature of the Rural Districts is such, that a great proportion of the upgrown population must consist of Agricultural and other Labourers. In the facts here collected, they amount to 33 per cent.; and their lives being of higher value than the average lives in the district, it is no more fair to judge of the value of life and the influence of locality on the residue of the population from calculations involving the consideration of all the lives generally, than it would be just to compare the value of life in the Residue in the preceding illustration with Town

draw the conclusion that life in the Rural Districts was of less value than in the Districts; for in both cases a fictitious value is assigned, by being mixed up with a variable class.

From the preceding remarks it is evident that in particular occupations, even in the Rural Districts, life is of less value than in others. Those occupations cannot be said to be less healthy from the objectionable features peculiar to large Towns and Cities, for they must be supposed under very favourable circumstances for prolonged life. In Table H, No. 4, is given the expectation of life in sixteen trades in the Rural District, selected at random, without any previous knowledge as to whether they were healthy or otherwise. An inspection of this Table will shew, that in those sixteen trades, (namely, Plumbers Painters and Glaziers, Weavers, Butchers, Millwrights, Stonemasons, Cabinet-makers, Printers, Bakers, Bricklayers, Wheelwrights, Tailors, Cordwainers and Shoemakers, Sawyers, Clerks, Carpenters and Joiners, and Blacksmiths,) the value of life is less than the average for the whole Rural Districts; and Labourers were before shewn to be more healthy than the average results. It is therefore clear, that if a given District were chiefly made up of the class whose lives are above the average value, or of those below it, that the general results for that District would be of high or low value accordingly.

A very small portion of the population in either the Town or City Districts can follow agricultural pursuits; and therefore the standard of life in those Districts will be lowered in consequence of that circumstance alone; but on further examination it will be found that the comparative value of life in those Districts is not only lowered in consequence of the absence of many of the most healthy occupations common to the Rural Districts, but that it is still further decreased by the presence of some of the most unhealthy employments, not to be found, or at least to a very limited extent, in the Rural Districts. In other words, the effect of the occupations is such, that if the same people were placed in the Rural Districts, no matter over how much surface they were spread, in order to avoid the influence supposed to connect itself with the congregation of large numbers into towns, still the mortality would be much higher among the people thus conditioned, than among the average of the rural population in ordinary circumstances.

If the view brought forward be correct, that the mortality of Towns and Cities is increased from the existence of a high proportion of trades which are in themselves unhealthy, independent of the influence of the locality, it should follow that the difference found by a comparison of the rate of mortality of a given number of trades in one district, with that of the same trades in another district, should be less than the difference between the rates of mortality for the general results of the same districts. If the differences of the decennial periods from 10 to 70 in the general results for Rural and Town Districts be taken, the sum of the differences will be found to amount to 19.3299 years; but the sum of the differences at the corresponding periods for the 16 Trades formerly referred to is

only 16·3868 years; being less than the other by about 15 per cent. For a like reason it should follow, that if the differences at the same periods between the 16 Trades, and the general results of each district be taken, they should amount to less in the Town than in the Rural Districts; and accordingly in the Rural Districts the sum of the differences is found to be 4·7029 years, while in the Town Districts it is only 1·7598 years.

In order to afford still further evidence of the effect on the average value of life by the prevalence of particular trades, a few other cases will be submitted; and to render the illustrations more simple they will be given for the average of the Three Districts, or rather with the Three Districts conjoined; and consequently they must be brought into comparison with the General Results for the Three Districts as given in Tables F and C.

An inspection of Table I will shew that the equation of life in Miners is at Ages 61-2; in Bakers, at Ages 59-60; Plumbers Painters and Glaziers, at 56-7; and Clerks, at so early a period of life as 51-2. In F, for the Three Districts combined, the same results appeared at Ages 66-7, shewing a difference of 5, 7, 10, and 15 years respectively; and the following Abridgement of Table J will shew the marked difference in the expectation of life in these employments at five decennial periods.

| Age. | Rural, Town,<br>and<br>City Districts.<br>G. | Clerks.<br>J, No. 2. | Plumbers,<br>Painters, and<br>Glaziers.<br>J, No. 3. | Bakers.<br>J, No. 4. | Miners.<br>J, No. 5. |
|------|----------------------------------------------|----------------------|------------------------------------------------------|----------------------|----------------------|
| 20   | 43·7736                                      | 31·8347              | 36·9040                                              | 40·0268              | 40·6700              |
| 30   | 36·6051                                      | 27·5761              | 30·5082                                              | 32·3572              | 33·1573              |
| 40   | 29·3306                                      | 21·8573              | 24·3046                                              | 24·4756              | 24·9204              |
| 50   | 22·1920                                      | 16·0465              | 17·0955                                              | 19·0910              | 17·5346              |
| 60   | 15·6942                                      | 12·4264              | 12·1675                                              | 14·0632              | 11·8590              |

The very remarkable difference between the above employments and the General Results, cannot fail to occasion some surprise; and at the same time conclusively prove, that any district containing a majority of the above, or other equally unhealthy employments, must shew a very reduced average value of life for the district, independent of the influence of the local situation itself on health.

It will no doubt cause some uneasiness in the minds of inquirers to find, that so highly important and industrious a class of men as Clerks should stand lowest in the scale of the above employments; and that from 20 to 60 their expectation of life should be only 75 per cent. of the general average. A solution of this will hereafter appear. The expectation of life among Plumbers Painters and Glaziers in the same period is equal to 81 per cent., Miners 85 per cent., and Bakers 88 per cent. of the general average.

Plumbers Painters and Glaziers will be found next in the scale; and although much

below the general average, they are still of considerably higher value than the class designated Clerks.

Bakers, as well as the preceding class, have long been supposed to be unhealthy: and although no attempt had hitherto been made to ascertain the precise value of their lives, it is thought that the present results will shew a much greater difference than would be generally calculated upon. The class Miners will be found to rank above the three others at the early periods of life, but below them at the latter periods of life.

The remark formerly made should be here kept clearly in view, that the difference found by a comparison of any class with the general results will always be less than the actual difference; and therefore the effect which the preceding and other unhealthy employments have in reducing the average rate of mortality, is still greater than what appears by the preceding Table.

Some large towns or cities are known to represent a less value of life to their inhabitants generally than other towns; and the explanation usually given of this difference has been the favourable or unfavourable nature of the locality, and a change in the sanitary regulations of the place looked forward to as a certain remedy; but a minute examination of all the external circumstances affecting life will shew, that the great diversity in the mortality of certain classes arises from the influence of other agents. In Table H, No. 2, is given the expectation of life calculated from the combined data of all trades in Liverpool; and a comparison of this with the general results for the Rural Districts will shew a much greater difference due to locality in the apparent sense, than has hitherto been shewn by any other tables of the value of life in different localities; but at the same time it will be seen that this difference falls much short of the actual difference between different employments." At Age 30 the difference between the expectation of life in the Rural Districts and in Liverpool is 8·2636 years; but the difference between Clerks and Labourers is 13·0211 years; and so also at other periods of life. It ought to be understood, that in making this comparison, the influence of employment is shewn to disadvantage; for, as has been already pointed out, every large town has its average lowered by the influence of certain trades; and therefore the actual difference in the above comparison between the Rural Districts and Liverpool is less than there given: and again, in the comparison between Clerks and Labourers, the expectation for Clerks has been for the average of the three districts; but if it had been taken for the City Districts only, a much greater difference would have been found, and consequently the influence of employments appeared the greater.

From Table K, No. 2, it will appear that there is a uniform decrease in the specific intensity of life from the commencement to the end of the table. A comparison will shew that the specific intensities at ages 30, 40, and 50, correspond with the specific intensities at ages [45, 54,

TABLE K, No. 1.

| 54   | 57614   | 1926   | 3·3425                 | 29·913                 | 100  | 3       | 3      | 75·0000                | 1·333                  |
| 55   | 55688   | 1854   | 3·3282                 | 30·048                 |      |         |        |                        |                        |

45, 54, and 63 in the Rural Districts; Ages 38, 49, and 57 in the Towns; Ages 29, 42, and 59 in the Cities; and at Ages 39, 51, and 61 in the Three Districts combined. A further inspection of the same table will shew that half the population dies off between the ages 58-9,—an earlier period than in the City Districts of Table F by 3 years.

In Table H, No. 2, the expectation of life for all trades in Liverpool will be found to be lower than the expectation given in Table G for the City Districts generally. The following shews the difference at decennial periods of Life.

| Age. | City Districts.<br>Table G. | Liverpool. | Difference. |
|------|-----------------------------|------------|-------------|
| 20   | 40·0148                     | 37·9553    | 2·0595      |
| 30   | 32·8603                     | 30·1437    | 2·7166      |
| 40   | 26·0873                     | 23·1524    | 2·9349      |
| 50   | 19·9271                     | 17·0946    | 2·8325      |
| 60   | 13·7685                     | 11·9626    | 1·8059      |

So far as a general inspection of the above results would suffice, it might be inferred that Liverpool is less healthy than the average of the large cities in England; but it is necessary here again to keep in view the peculiar aggregation of employments which are in themselves unhealthy, independent of the locality; for it so happens, that the class of Labourers in large cities is subject to a very high rate of mortality, and that the peculiar business of Liverpool occasions a great preponderance of that class in the dock, and other employments of that kind, a large proportion of which enters into the above results.

It has been shewn in Table F, for the Three Districts, that the expectation of life for Members of Friendly Societies over the country generally, is higher than that for the whole population of England and Wales as given in Table D. In like manner it will also be found, that the expectation of life among the Members of Friendly Societies in Liverpool is also higher than the expectation for the general population of Liverpool.

At page XXVII. of the 5th Report of the Registrar General will be found a table of the Expectation of Life for the Town of Liverpool; and assuming that it gives a correct representation of the value of life of the whole population, we shall find the comparative value of life between the Members of Friendly Societies and the general population in the following Table:—

| Age. | Expectation of Life in<br>Liverpool. |                   | Difference in favour of<br>Friendly Societies in Liverpool. |           |
|------|--------------------------------------|-------------------|-------------------------------------------------------------|-----------|
|      | Friendly Societies.                  | Whole Population. | In Years.                                                   | Per Cent. |
| 20   | 37·9553                              | 33·0000           | 4·9553                                                      | 15·0160   |
| 25   | 33·9067                              | 30·0000           | 3·9067                                                      | 13·0223   |
| 30   | 30·1437                              | 27·0000           | 3·1437                                                      | 11·6433   |
| 35   | 26·5260                              | 23·0000           | 3·5260                                                      | 15·3303   |
| 40   | 23·1524                              | 21·0000           | 2·1524                                                      | 10·2500   |
| 45   | 19·9908                              | 18·0000           | 1·9908                                                      | 11·0600   |
| 50   | 17·0946                              | 16·0000           | 1·0946                                                      | 5·6922    |

A careful consideration of all the preceding observations, it is believed, will be sufficient to shew that the excessive mortality of the general population of Liverpool must be due to some other cause than simply that of locality. The persons over whom the observations in the first column extend, being members of Friendly Societies, and almost exclusively workmen and mechanics, of necessity inhabit the inferior class of houses, in the worst conditioned streets; and it is therefore impossible that they can escape the contagious effect of the pestilential diseases supposed to be the scourge of unhealthy neighbourhoods: and admitting this, the results given for the Friendly Societies must evidence all the legitimate effects due to locality; and therefore the excessive mortality of the general population is due to some other cause—such as the poverty and distress which, unhappily, are allowed to remain so much neglected in the large manufacturing and commercial towns of the kingdom. If any part of this argument were to be met by the statement, that the higher expectation of life given for the members of Friendly Societies in Liverpool than for the general community, may be accounted for by the omission of some very unhealthy trades; this would be sufficiently answered by the fact, that 175 employments are included, and, as has already been shewn, some of them the most unhealthy occupations; so that a fair average may be said to be taken. A similar objection might also seem to apply against the general results for the whole kingdom; but if it is recollected that upwards of four hundred trades are included, the force of the objection will disappear.

It is evident from all that has been said, that the peculiar sanitary condition of large towns has not the remarkable effect which many have supposed in shortening the duration of life; still, it has some effect, and the nature and extent of that influence it is important to understand. But a rude estimate only can be made, until the value of life in every important employment, occupation, or trade has been investigated, for the various localities or districts, on some such plan as that given in the present paper; and then grouping or classifying a given number of these common to different localities: the result arrived at would shew the precise amount of influence which a particular District, City, or Town, has on the duration of life. A partial or limited comparison of a few trades would not be adequate to answer definitely this question, but an accurate combination of a sufficiently large number of trades, to guard against the effect of fluctuation.

In the beginning of this Paper it was stated, that to carry out the question in this extended degree was a task of too imposing a nature on the present occasion; and that such illustrations would only be brought forward, as would be necessary to solve the more immediate question.

On the general mortality of large towns especially, little confidence should be placed, even although every other precaution as to distinction of age and other conditions be taken; for fallacies from two sources are apt to enter:—First, if, in comparisons of large towns,

precisely the same classes of trades do not exist, errors will arise from that circumstance ;— and in the second place, although the same classes of trades do exist in both places, unless the proportionate numbers to the whole population be the same, errors in the result must arise. The nature of the error in the first case is plain, from the fact that different trades are in the same place influenced by different rates of mortality ; and if any given trade is wanting, its tendency to alter the general average will be lost. The error in the second case is of a like nature ; for if the absence of the whole class affect the general result, the absence of a fraction of that class must also affect it, although not to the same extent. Illustrations confirmatory of this have already been given when discussing the influence of the class of Labourers, and also the Sixteen Trades combined, on the general averages for the respective Districts ; and a recurrence to those illustrations will be sufficient to shew the truth of the present observations.

An inspection of TABLE K, No. 1, will shew the Rate of Mortality for Female Life among the Members of Friendly Societies in England and Wales, for the Rural, Town, and City Districts combined. The Tables for Male and Female Life here given, seem to possess in many respects the same relation as those given for Male and Female Life generally in England and Wales ; the Specific Intensity at the earlier periods being higher for Male than Female Life, crossing each other at the middle periods, and turning in favour of Female Life at the advanced ages. It will be seen that the Male Population of Table F for the Three Districts is bisected at 66–7, and that the Female Population in Table K, No. 1, is also bisected at the same period of life. In the general population of the country the same thing takes place a year later among Females than among Males.

The Expectation for Female Life, for the general results of Friendly Societies, will be found in Table H, No. 1 ; and the following Abstract will shew the relative value of Male and Female Life in the country generally, as well as in Friendly Societies :—

| Age. | Expectation of Life in England and Wales. |          |             | Expectation of Life among<br>the Members of Friendly Societies. |          |             |
|------|-------------------------------------------|----------|-------------|-----------------------------------------------------------------|----------|-------------|
|      | Males.                                    | Females. | Difference. | Males.                                                          | Females. | Difference. |
| 20   | 40·6910                                   | 41·5982  | ·9072       | 43·7736                                                         | 45·2640  | 1·4904      |
| 30   | 34·0990                                   | 35·1671  | 1·0681      | 36·6051                                                         | 38·1841  | 1·5790      |
| 40   | 27·4760                                   | 28·7330  | 1·2570      | 29·3306                                                         | 30·7813  | 1·4507      |
| 50   | 20·8463                                   | 22·0545  | 1·2082      | 22·1920                                                         | 23·8200  | 1·6280      |
| 60   | 14·5854                                   | 15·5230  | ·9396       | 15·6942                                                         | 17·2380  | 1·5438      |
| 70   | 9·2176                                    | 9·8409   | ·9376       | 10·2057                                                         | 10·9750  | ·7693       |

It will thus be seen, that the distinction between Male and Female Life among the Members of Friendly Societies, differs very little from that between the sexes in the country generally ; and this difference would be considerably reduced if the necessary corrections for employments were made, as the data for Male Life in Friendly Societies

will be composed of a much higher proportion of unhealthy trades, in relation to the whole male population of the country, than the data for Female Life in comparison to the whole female population. This coincidence of course tends to strengthen the confidence to be reposed in both classes of results, and brings forward an additional argument against the sufficiency of certain inquiries hitherto made, shewing in some instances so wide a distinction between the value of life in the sexes.

In a subsequent portion of the present edition of these contributions a large amount of additional data will be found introduced, bearing directly on particular classes of society, and supporting in a very decided and conclusive manner the views developed by the preceding facts as given in the first and second editions. It is, however, thought better not to interfere with the original course of argument by introducing the new matter at this place, and it is consequently reserved for a more advanced part of this paper.

| Age | Male   | Female | Male   | Female | Male   | Female |
|-----|--------|--------|--------|--------|--------|--------|
| 10  | 10.000 | 10.000 | 10.000 | 10.000 | 10.000 | 10.000 |
| 20  | 10.000 | 10.000 | 10.000 | 10.000 | 10.000 | 10.000 |

## DURATION OF LIFE IN SCOTLAND.

A SEPARATE set of returns was procured from Societies in Scotland, and the facts embodied in them have been combined into a distinct class of tables, to which reference will be presently made. The results thus derived will be of the more importance, as serving to confirm those obtained from the English Societies; and their value in this respect is enhanced by the fact, that the Scotch returns extend over a period of twelve years, while those by the English Societies were limited to five years. The Scotch returns were also made under quite different circumstances from those of the English, and they thus act as checks on each other. The nature and extent of the original form in which the information was furnished by the returns from Scotland, have already been referred to.

TABLE L represents the results for the Scotch Societies, in precisely the same manner that Table E did for the English Societies. The places forming the respective Districts in Scotland will be found in the Appendix, Note III.

TABLES M and N were subsequently formed from Table L, in the same manner in which Tables C and D were formed from B, and Tables F and G from E. An inspection of TABLE M for the Rural Districts, will shew that the Specific Intensity increases in a uniform ratio, from the earliest age in the Table to the extreme of life. A comparison with the Rural Districts of England (Table F) will shew a higher Specific Intensity in the Rural Districts of Scotland till age 34; but from that till age 54 it is lower in Scotland, and from 54 to the end of the Tables the Specific Intensity is sometimes higher and sometimes lower. A more general and comprehensive view of the two Tables will be obtained by comparing the Equation of Life: for age 10 it takes place between the ages 67-8 in the Rural Districts in Scotland, but between ages 68-9 in England. Again the Equation for age 30 takes place in both Tables between 70 and 71. Considering the different sources from which the data of the two Tables are derived, and the different periods of years over which the observations extend, the agreement of the Tables in this respect is somewhat remarkable.

|      |              | 70542       |              | 1063        | 1.5069    |              | 154261.847  | 2.1868     |      |

In the Town Districts of Scotland, half the population dies off at the ages of 65-6; but in the Town Districts in England, the same thing takes place a year earlier. It is in the City Districts of Scotland that the most marked difference is found; but when it is recollected that the only places included in the list of Scotch Cities are Edinburgh, Glasgow, Paisley, and Aberdeen, and that the observations relate chiefly to the three first-named places, it will in some measure account for the very high rate of Mortality. An inspection of the City Districts of TABLE M will shew a much lower specific intensity for Scotland up to age 60, than even for Liverpool; but from that age to 80 it is higher than in Liverpool. In the City Districts for Scotland, half the population dies off between the ages of 53-4, being eight years earlier than in the City Districts of England, and five years sooner than in Liverpool, and in fact coming very close to the very worst class of results in England—namely, Clerks—in which half the population was cut off at ages 51-2. But as the numbers over which the observations extend in the City Districts in Scotland are limited, less confidence might reasonably be placed in the results, and the excessive mortality in part assigned to the fluctuation to which small numbers are subject.

On examination, however, of the various groups of results making up the whole class for the City Districts, they were, without exception, found subject to a high rate of mortality, thus carrying evidence of a higher absolute mortality than in the average of English Cities.

The results for the Three Districts combined shew a less specific intensity than in England up to age 66, and from that age upwards, the Tables cross each other. In the general results for Scotland, half of the population dies off between ages 64-5; but in the general results for England, that event is deferred two years beyond that period.

Looking next to the Expectation of Life, as given in TABLE N, it will be found that in the Rural Districts of Scotland it is less than in England by about half-a-year, from ages 20 to 75; but the Town Districts of Scotland give a higher Expectation than in England till beyond 70 years of age, and the City Districts of Scotland shew a lower Expectation of Life than Liverpool up to about 50 years of age. In order to admit of better comparison, the general results for the Three Districts in Scotland and England will be arranged as follows for decennial ages.

| Age. | Expectation of Life in Friendly Societies in |          | Difference in favour of<br>England in Years. |
|------|----------------------------------------------|----------|----------------------------------------------|
|      | Scotland.                                    | England. |                                              |
| 20   | 42.7218                                      | 43.7736  | 1.0518                                       |

From a consideration of these results, it will be seen that the Rural Districts of the two countries have shewn the nearest approximation; and this is precisely what might have been anticipated from a careful consideration of the elements entering into the formation of the respective Tables. In the Rural Districts of all countries, the condition of the population, as to occupation and employment, is more nearly the same than in the Town or City Districts; and since employment has been shewn to have so important an effect on the Duration of Life, the rates of mortality should differ less in the Rural Districts, where less diversity of employment exists. Before, however, fixing definitely on the Scotch Cities so high a rate of mortality as that shewn in Table M, it should be kept in view that one very important element of the investigation has not yet been touched upon. In considering the condition of the English Cities, it was shewn how an accidental combination of certain trades would produce a very different result from the fair average of the general population; so also, in the present comparison of the Scotch with the English Cities, may an excess of particular trades, not common to both Districts, or not existing in both Districts in the same ratio, modify the results. The inquiry will therefore not be complete till similar trades in both Districts be compared. To enter further, however, into that question would, as already stated, be to go beyond the limits assigned to this paper.

But as some curiosity may naturally be excited by the marked difference in the value of life, as shewn in the preceding Table, between the Scotch and English Cities, it has been thought of sufficient importance to form Mortality Tables for the general population of the City of Glasgow, in order to compare the results with English Cities.

These Tables—viz. O, P, Q, and R—have been formed exactly in the same manner as Tables A, B, C, D. It is therefore not necessary to enter further into that part of the question, than to state that the basis of the Tables are the Mortality Bills for the City of Glasgow for the ten years 1832-1841, and the population as enumerated in 1831 and 1841.

An inspection of TABLE Q will shew that of the male population of Glasgow alive at Age 10, one half is cut off between the ages 48-9, which is

20 years earlier than among Friendly Societies in the Rural Districts of England.

19 ... .. Scotland.

17 ... .. Town ...

16 ... .. England.

13 ... .. City ...

5 ... .. Scotland.

3 ... .. Clerks, which was the worst class

of results formerly arrived at.

If the nature of this paper permitted a more extended review of all the facts presented

| 55   | 43819   | 1696   | 3.8709                 | 25.833                 |      |         |        |                        |                        |

many remarkable coincidences would be seen to have taken place, and one among these must be already obvious. The general results for Friendly Societies in England and Wales were found to be more favourable to life than the results for the whole population of England and Wales, and that in both sexes; so, also, were the results for the Members of Friendly Societies in Liverpool more favourable than those for the whole population of Liverpool; and here it will likewise be seen that the mortality of the general population of Glasgow is greater than among the Members of Friendly Societies in the City Districts of Scotland.

The difference between the Equation for Age 10 in Male and Female Life for the whole population of Glasgow is 3·125 years, while in the general population of England and Wales it is a little above one year. This suggests the mention of another feature which presents itself in this enquiry. It appears that the higher the absolute value of Life in any class of results, the less distinction will there be found between Male and Female Life. Thus—

|                              | { | Whole Population of Glasgow . . . . .             | Females = 41·346 |                         |
|                              |   |                                                   | Males = 38·221   | —diff. = 3·125 ...      |

If comparisons were made between the sexes in the intermediate classes of results, a development of the same feature would be seen. As has already been stated, where the Duration of Life is reduced below its average standard by the prevalence of unhealthy occupations, the influence will be more strongly felt in the male than in the female sex.

If the expectation of Life for the City of Glasgow, as given in TABLE R, be now referred to, the remarkable depreciation in the duration of life there will appear somewhat startling. No Table of Mortality hitherto published has shewn any thing like so low an estimate. Liverpool has been frequently referred to as an example of the short Duration of Life; but a comparison of the Expectation of Male Life for Liverpool, as given at page 59, with the results in Table R, will shew

| 55   | 12.1831                    | 13.4333  | 14.4014                   | 15.7186  |      |                            |          |                           |          |

The mortality of a population like that of Glasgow is subject to remarkable fluctuations, shewing an extreme difference in some years of about 68 per cent., or a mean fluctuation of about 32 per cent. An inspection of the total male deaths for all ages, for each of the ten years 1832—1842, will render this evident.

|                      |   |   |      |                      |   |   |      |
|----------------------|---|---|------|----------------------|---|---|------|
| Total Deaths in 1832 | . | . | 4811 | Total Deaths in 1837 | . | . | 5423 |
| ... 1833             | . | . | 3229 | ... 1838             | . | . | 3490 |
| ... 1834             | . | . | 3255 | ... 1839             | . | . | 3898 |
| ... 1835             | . | . | 3726 | ... 1840             | . | . | 4470 |
| ... 1836             | . | . | 4334 | ... 1841             | . | . | 4514 |

It will further be seen that those remarkable fluctuations are due chiefly to the mortality in mature life, and not to the mortality in infancy, as some writers have believed.

| 1835    | . | 885                   | . | 365                           | 1840    | . | 1346                  | . | 404                           |
| 1836    | . | 1279                  | . | 115                           | 1841    | . | 1278                  | . | 381                           |

The preceding will shew, that while the extreme difference in the mortality from ages 20 to 50 is 125 per cent., for the first year of life it is only 32 per cent. If the mean fluctuation for ages 20 to 50 be taken, it will be found to be 53 per cent., while that for the first year of life is only 14 per cent. Were the inspection extended to the mortality of female life, similar results would be obtained. Notwithstanding the inferior numbers in infant life, the fluctuation is confined within narrower limits than the mortality of mature life; and this law is in obedience to the doctrine of probability, when applied to any other subject, as well as to the mortality of life. For whenever the intensity which determines any result increases—or in other words, when the probability of any event approaches unity—so also will the fluctuation in a series of events be reduced in amount.

It is evident from the preceding results of the Mortality in Glasgow, that a Table of the Expectation of Life calculated for one period of years—for example, the three years 1833, 1834, 1835—would differ widely from a Table founded on the results of the succeeding period of three years, and that the next succeeding period of three years would also differ in a marked degree from either of these: it has on that account been thought the better course to embrace the results of the whole ten years. On a previous occasion, a Table of the Expectation of Life for the five years, 1836—1840, had been calculated; and the results were for ages

$$20 = 27.624$$

$$40 = 21.711$$

$$50 = 16.590$$

bringing the Expectation of Life above that given for the whole population of Liverpool,

in the Fifth Report of the Registrar General. It would therefore be rash to conclude that the public health of Glasgow is inferior to that of Liverpool; for if the same means existed of calculating the mortality of Liverpool during the ten years to which the results for Glasgow relate, it might then be found that the Expectation of Life, on an average of that number of years, was overstated by the Registrar General, whose figures were derived from the mortality of one year only.

In the Tenth Report of the Registrar General he has given the mortality of Liverpool for the seven years 1838-44, and the results will be found to fully bear out the views originally entertained in the preparation of this paper, as is evident from the facts contained in the following abstract, shewing the mortality per cent. in Liverpool, deduced from the Deaths for 1841, and also from the Deaths for the seven years 1838-44.

| Age.      | MORTALITY PER CENT. |          | Age.      |
|-----------|---------------------|----------|-----------|
|           | MALES.              |          |           |
|           | 1841.               | 1838-44. |           |
| 10 to 14  | ·654                | ·631     | 10 to 14  |
| 15 ... 24 | ·935                | ·987     | 15 ... 24 |
| 25 ... 34 | 1·239               | 1·268    | 25 ... 34 |
| 35 ... 44 | 2·215               | 2·162    | 35 ... 44 |
| 45 ... 54 | 3·261               | 3·367    | 45 ... 54 |
| 55 ... 64 | 5·298               | 5·305    | 55 ... 64 |
| 65 ... 74 | 9·644               | 10·634   | 65 ... 74 |
| 75 ... 84 | 17·422              | 20·740   | 75 ... 84 |
| 85 ... 94 | 19·713              | 32·230   | 85 ... 94 |

It is hence very desirable that our national records should be immediately made available to every inquirer into Vital Statistics, that the incorrect conclusions heretofore so generally drawn from limited observations, even under official sanction, may be supplanted by others founded on an enlarged and more carefully collected body of facts.

An inspection of TABLE R will shew that Female Life in Glasgow, as elsewhere, is of higher value than Male Life.

|                               | At Age 30. | At Age 40. | At Age 50. |

| 100 and upwards. | 0           | 2                              | 0          | 19          | 2                              | 10.5263    | 100 and upwards. |
|                  | 276056      | 7454                           | 2.7000     | 324129      | 7531                           | 2.3234     |                  |

The preceding results seem to point out a higher rate of mortality as pervading all the groups of observations brought into comparison from Scotland; and it is therefore to be regretted that the Registration Act does not extend to that country, and afford a certain means of solving so important a question. The subject, however, in its present state, has been thought of sufficient importance to warrant the calculation of Mortality Tables for the Town of Dundee; and accordingly TABLES S and T have been deduced from the Mortality Bills of that Town for the ten years 1835–44, and the Census of the Population in 1841, on the principles described for the formation of Tables B and C. The Expectation of Life, as resulting from these Tables, will be found in Table R.

An inspection of TABLE T will shew that in Dundee the Equation of Male Life for Age 10 takes place at Age 55–6, which is seven years beyond the results obtained in Table Q for the whole population of Glasgow, and even two years higher than the [Equation of

TABLE T.

TRADES NOT CLASSIFIED—DUNDEE—*Males*.

Equation of Life for the Members of Friendly Societies in the average of the Scotch Cities. This result will no doubt be unexpected by some inquirers, as Dundee has usually been held up as the type of unhealthy Cities; but the present results shew the necessity of extended observations before drawing any conclusions, the remarks made relative to the fluctuation of Mortality in Glasgow being equally applicable to Dundee. The following Abstract will give the comparative value of Male Life in the gross population of Glasgow, Liverpool, and Dundee.

| Age. | Expectation of Life in |                                                    |                     | Age. |
|------|------------------------|----------------------------------------------------|---------------------|------|
|      | Glasgow,<br>Table R.   | Liverpool,<br>Reg. Gen. page xxvii.<br>5th Report. | Dundee,<br>Table R. |      |
| 20   | 30.9665                | 33.0000                                            | 35.9632             | 20   |
| 25   | 27.8512                | 30.0000                                            | 32.4423             | 25   |
| 30   | 24.8998                | 27.0000                                            | 29.0866             | 30   |
| 35   | 22.1102                | 23.0000                                            | 25.8297             | 35   |
| 40   | 19.4532                | 21.0000                                            | 22.7017             | 40   |
| 45   | 16.9366                | 18.0000                                            | 19.8168             | 45   |
| 50   | 14.5350                | 16.0000                                            | 17.0891             | 50   |

The value of life in Dundee will thus be seen to stand higher than in either of the other Cities. If a complete system of Registration existed in Scotland accurate means would be afforded of carrying out a satisfactory inquiry as to the relative value of life in different Districts; but so far as the more imperfect system of Local Registration will admit of judging, it does not appear that the Duration of Life in the large Towns of Scotland should be regarded as so much below that of Cities in England.

Since the preceding paragraphs were written, in 1845, several ineffectual attempts were made to introduce a system of Registration into Scotland, but after many difficulties an Act was at last carried, namely, "The 17th and 18th Vict. c. 80," and which came into operation on the first day of the present year. It is at the same time satisfactory to find that the Legislature has availed itself of the experience gained under the English Registration Act, and has thereby provided for Scotland a Registration system commensurate with the views of those having a practical acquaintance in working such measures. The results will in a few years furnish to scientific inquirers that amount and character of data which are so necessary to the complete solution of many important political and social problems of the times.

It is deemed desirable to insert here the following Report of a Committee of the Statistical Society, consisting of Colonel Sykes, Dr. Bowring, Mr. Fletcher, Mr. Farr, and Mr. Neison.

*Report of the Registration Committee to the Council of the Statistical Society, 5th June, 1847.*

THE Scottish Registration Committee appointed by the Council on the 13th March, 1847, "to consider certain Schedules and Provisions of the proposed Registration Bill for Scotland, to recommend Forms, and to communicate with the proper Authority on the subject;" beg to report, that the Committee, at their Meeting on the 16th March, 1847, on examining the proposed Registration Bill, found the Schedules defective in the following particulars, viz.:

**In Marriage Schedule—**

1. The usual and present residence of the parties omitted.
2. Their ages not given; the parties being inadequately distinguished as "Minors," and of "Full Age."
3. The professions of the parties are omitted, while those of their parents are given instead.
4. "Civil Condition" given, but it would be worth while, in the case of widows and widowers, to know when the parties became such, and how often.
5. The number of children of each party by former marriage not obtained.
6. The place of birth of the parties marrying not stated.
7. The father's name only given, whereas the names of both parents should be furnished.

**In Births' Schedule—**

1. The items to determine child's identity, inadequate.
2. The birth-place of the parents omitted.
3. The marriage-place of the parents not given.
4. The number and sex of former children omitted.
5. The signatures of the parents from the Register Book should be required.
6. The certificate of the accoucheur, nurse, or persons present is omitted.
7. The place of registry omitted from the entry.

**In Deaths' Schedule—**

1. The arrangement of the name and description incomplete.
2. A certificate signed by the medical attendant should be required, stating the cause of death, and when the party was last seen by him.
3. The burial place and undertaker's name are omitted.
4. Place of birth and time of residence in the district omitted.
5. The rank or profession, and names of the parents omitted.
6. No statement as to whether married, to whom, at what age, or where.
7. Issue of the marriage living and dead, and the name and age of each should be furnished.
8. The signature of a witness, as well as of the informant, is wanting.

To remedy the defects now pointed out in the Schedules printed with the proposed Bill, the Committee suggested the substitution of the following three forms of Schedules, A, B, and C:—

[In order

# SCHEDULE A—MARRIAGES.

| COUNTY—Middlesex. |                                                                                                                                                                   |                            | DISTRICT—Marylebone.     |                          |                     | 1847. W. Gagen, Registrar, March 3rd, 1847. |

In order to determine whether any practical difficulties might be found in eliciting for registration the various facts required in those forms, the Committee caused an experiment to be made in several districts of the metropolis, and it was found that all the information needed could be readily obtained from the public, no objection arising on furnishing it. The results of this attempt at practically working out the Schedules were submitted to the Committee, and considered as satisfactory evidence that no insuperable difficulties existed in the way of carrying out the plan on a national scale. Copies of the three Schedules referred to were forwarded to Sir George Grey and the Lord Advocate of Scotland, and subsequently a deputation from the Committee waited on the Lord Advocate, and explained that the object which the Council had in view was simply to assist in securing for Scotland such a form of registration as the present advanced state of statistical science seemed to demand; and believing that a more complete and useful form of registry than that required under the proposed Bill might without difficulty be carried out, the Council of the Statistical Society was anxious that the people of Scotland should possess that system of registration which was best calculated to exhibit their true social and civil condition.

The attention of the Lord Advocate was next directed to the defects in the Schedules of the Bill then passing through the House, and the advantages which it is believed would arise from the adoption of the proposed Schedules A, B, and C were pointed out. Throughout the interview the Lord Advocate entered most fully and minutely into the arguments brought forward by the deputation, and promised to give the whole subject his particular consideration, although he could not engage to adopt all the suggested alterations; and he further expressed it as his opinion, that the better plan would be to pass the present Bills with but little alteration in the Schedules, and to introduce such provisions as would enable the competent authorities, with the sanction of the Queen in Council, to make such alterations and improvements in the modes of registration as experience may shew to be necessary and expedient.

Subsequently to this interview, it was considered advisable to forward Schedules, on the model of those suggested, for use to some district of Scotland in order to discover whether any difficulty was likely to arise in that part of the kingdom, with respect to the peculiar form of registration suggested. Dr. Watt, of Glasgow, who has had great experience in such matters, kindly undertook to practically test the Schedules in that city, and the Committee, at its meeting on the 15th ultimo, was furnished with the results obtained by Dr. Watt, consisting of a number of Registrations of the "Private Burials in the Cathedral burying-grounds," of "Poor buried at the public expense," and of "Burials by the Royal Infirmary of Glasgow." The following extract from a letter of Dr. Watt, will shew that he considers no difficulties exist in the way of getting the Schedules filled up:—

"As Mr. Farr did not state the time at which he wished the enclosed schedules returned to him, I have delayed making the returns till they could be filled up for a complete month. I regret, however, that some little delay has taken place in obtaining the returns for the poor buried at the public expense, and from the Royal Infirmary. These schedules have been filled up by the parties who make the returns for the Glasgow Mortality Bills, and who receive very small salaries for their respective labours. They offered to make out clean copies of the schedules, but I think it better to transmit them off hand in their original state.

"It will be observed that some of the lists are not so complete as could be wished. This arises from the informants not being aware that so much information was required of them. Were it known to the public that the various particulars stated in the schedules were required, I have no doubt but they could, without difficulty, be filled up with accuracy for Glasgow. *From what I know of the subject, I have no doubt but they would be filled up with perfect accuracy, provided care is taken to appoint properly qualified persons as registrars.*"

Your Committee was further of opinion that, in the event of such Schedules being adopted, great advantage would result to the public, by issuing forms of certificates embodying the principal facts intended to be set forth in the Schedules themselves, and that they should be delivered, by the respective Registrars, to the parties interested on the various occasions of Marriage, Birth, and Death. That these should be regarded as the "Original Certificates," and have appropriate counterparts, and that no other original certificates should ever be issued of any one of these events, but that any other documents of a similar kind which might be issued should only be a certified copy by the proper Registrar.

(A.)

## CERTIFICATE OF MARRIAGE.

DISTRICT, Marylebone. No. in Register, 11.

On March 3rd, 1847.

At Marylebone Parish Church.

MARRIAGE, *after Banns*, was solemnised between us, according to *the rites and ceremonies of the Established Church*.

SIGNATURE, *William Hastings*.

### CERTIFICATE OF DEATH.

DISTRICT, *Poplar.* SUB-DISTRICT, *Poplar.* No. in Register, 1746.

NAME { *William Canty.*  
           rank or profession, *dock labourer.*  
           sex, *male.*  
           age, 62.  
           died on the 28th of February, 1847, 6½, A.M., at 16, *Cottage Row.*

CAUSE OF DEATH, *Pneumonia, two months*, as certified by *H. Bloomfield*, who last saw deceased February 27th, 1847.

Burial place, *Catholic burial-ground, Wade Street*, as certified by *M. Rutley, undertaker.*

BORN AT *county of Cork, Ireland; lived in this district, 36 years in Poplar.*

Parents' names and } Father—*Timothy Canty, shoemaker, dec.*  
rank or profession, } Mother—*Mary Canty, M. N. Nicholas, dec.*

MARRIED in the *parish of Scrill, Ireland, at the age of 22, to Honora M'Carty, by whom he had*

ISSUE, (1) *Timothy, 31, (2) William, 30, (3) Mary, 29, (4) John, dec. at 27, in 1846, (5) Catherine, dec. at 1, in 1820, (6) Stephen, 21.*

INFORMANT, *Honora Canty, her × mark, widow.*

WITNESS, *Mary Canty, daughter.*

REGISTERED on March 3rd, 1847, by *T. W. Gagen, Registrar.*

The Committee, after having given much attention to this subject, are convinced that the adoption of the proposed system of registration possesses scientific and legal merits beyond those of any other yet proposed in this country, and they regret that the framers of the Registration Bill for Scotland have not wholly concurred with them in their view of the question. As it is now understood, however, that the Bill will not pass during the present session of Parliament, and that the whole is likely to be further considered, it is to be hoped, from the willingness which the Lord Advocate evinced to introduce an efficient mode of registration, that reason will be found hereafter to carry out the system proposed by your Committee.

*5th June, 1847.*

On referring to the Schedules of the Registration Act for Scotland, the 17th and 18th Vict. c. 80, it will be found that they are almost identical with the preceding forms recommended for adoption by the Committee of the Statistical Society, and it is to be hoped, that the advantages to arise from so complete a form of Registration, will induce the Legislature to extend the improvements to the system now in use in England. It is very likely that in the first attempts to carry out these Schedules some difficulties will be experienced in Scotland, where no National Registration formerly existed, and during the first few years, the people will need to be instructed as to the precise kind of information required to be furnished in the event of a Birth, Death, or Marriage. At the date of the Committee drawing up the preceding Report, the practicability of the scheme was tested by Mr. Farr personally, in two different districts of the metropolis, and also by Dr. Watt in Glasgow, and the experiments fully satisfied the Committee that any attempt to carry out the system on a large scale must be successful, and that any difficulties which might be experienced at the beginning could only be of a temporary duration.

For many purposes, the mode of representing the value of life at various ages, under the expression "Expectation of Life," will be found inadequate. The method by which that value is obtained for a given age, involves the consideration of the decrements of life at every superior age; and therefore, in any Table, the Expectation of Life, even at younger ages, will be affected by the irregularities of mortality at the older ages. It

consequently sometimes happens that a comparison of different Tables, especially at the younger and middle periods of life, may shew an equal or nearly equal Expectation while there are in reality very different chances under the two Tables of living a given number of years; and again, Expectation Tables may shew very different values for the same age, when according to the nature of the data there are equal chances of living the same number of years.

From what has been said it will be seen, that although the "Expectation of Life" expresses the true average duration in years of a certain number of individuals at a given age, yet it does not represent the chances of surviving an equivalent number of years; and consequently, for medical and other purposes, in which it is required to determine the relative value, improvement, or other change which may have taken place within a given period of life, another expression must be found. The Equation of Life, which represents a term of years for which there is an equal probability of living, appears to be the best mode to determine the comparative value of life in different Classes or different Districts, within the same period of years, as the expression is affected by the mortality within those ages only. In order to shew the relation which the Equation of Life bears to the Expectation of Life, the expression under each form, corresponding to the decennial ages, are given for various classes of results in

TABLE U.

The terms in the respective columns headed Equation, were determined as follows:—

Let  $\epsilon_x$  = the number alive in the columns headed "Living" in Tables C, F, I, &c., &c., at the given age  $x$ .

Then  $\frac{\epsilon_x}{2}$  = the number alive at an advanced age  $x+n$  which will always be intermediate between the proximate years of age  $x+n-\phi$ , and  $x+n+1-\phi$  the fraction  $\phi$  of which is determined as follows:—

$$\lambda (\epsilon_{x+n-\phi} - \epsilon_{x+n}) - \lambda (\epsilon_{x+n-\phi} - \epsilon_{x+n+1-\phi}),$$

$$\text{or } \phi = \frac{\epsilon_{x+n-\phi} - \epsilon_{x+n}}{\epsilon_{x+n-\phi} - \epsilon_{x+n+1-\phi}}$$

$$\text{where } \epsilon_{x+n} = \frac{1}{2} \epsilon_x.$$

An inspection of Table U will shew, that at the earlier ages the Equation of Life always exceeds the Expectation, and at those ages there is always an even chance of outliving the period of years represented by the Expectation of Life; but the converse is the case for the older ages. It will be further seen, that in those Tables giving a higher absolute value to Life, the Equation retains its superiority over the Expectation till a more advanced period of years; or in other words, if the Equation and Expectation of Life in any Table be compared, the more advanced the period of life at which the two expressions approximate to equal values, the higher is the absolute value of life throughout that Table. An example of this will be seen in observing the respective terms for the City and Rural Districts, in the former of which the approximation happens ten years earlier than in the other: again, if the results for the Labourers in the Rural Districts be compared with the results for Clerks, thirty years' difference will be found; and on comparison of the results for other Classes in Table U, intermediate periods of approximation will appear.

## ON THE RATE OF MORTALITY IN THE MEDICAL PROFESSION.

RECENTLY I have had occasion to investigate the rate of mortality among two different classes of medical men; the one class being the Officers of the Medical Department of the Royal Army, and the other, the Members of the Royal Medical Chirurgical Society. The facts relating to the former were collected from the records of the Society formed for the benefit of the Widows of the Officers of the Medical Department of Her Majesty's Army, established in the year 1816, and the facts relating to the latter class were abstracted from the books of the Royal Medical Chirurgical Society, established in the year 1805.

The investigation, so far as related to the first group of facts, was required to be conducted with the greatest care and scrutiny, as the management of large pecuniary interests depended on the results. The utmost care was, therefore, exercised in this part of the analysis. Inquirers into vital statistics had not hitherto touched the question of the mortality among the members of the medical department of the army, but from their peculiar duties, and the varied climates to which so many of them are exposed, there was reason to believe that some unusual feature would shew itself in the mortality to which they are subject, and, therefore, under this conviction, it appeared absolutely necessary to determine, from the records of the Society, the rate of mortality to which its own members had been subject. After a somewhat laborious and very troublesome analysis of all the information procurable, the following exhibits the results arrived at. In the course of this analysis it was discovered that the social condition of the members had an important influence on the rate of mortality: and it was rendered necessary finally to exhibit the rate of mortality in connection with these conditions. It will be found that the results are not only exceedingly curious but of great practical importance.

In the following Table are exhibited the principal elementary facts from which to determine the rate of mortality among the members of the Society, who entered it unmarried, from its establishment, in 1816, until the 1st of January, 1851; excluding only such members as entered it in the married condition of life.

[The arrangement

TABLE I.  
*Mortality among Members entering Single.*

|          | 1,340                          | ..                                                                  | 15,567                                                 | 386      | 176         | 268           | 510      | 1,340           | 670.0    | 88.0        | 134.0              | 892.0    | 14675.0                       |

The arrangement of this Table is very simple, and will be readily understood by those giving attention to such inquiries; but to those not familiar with them, the following explanation may be useful.

Column (*a*) Represents the age at which each officer entered the society, or when some other event connected therewith took place.

(*b*) The number of officers entered at each age.

(*c*) The number of officers remaining under observation from each preceding age, and the residue of all those entering in each preceding age, who have not become subject to any of the contingent events represented in the adjoining columns. For example, three officers entered at the age of 17, and not falling under the events specified in the adjoining columns, they survive until the succeeding age, and come under observation as officers of the age of 18.

(*d*) Again, 1 officer entered at the age of 18, who, with the 3 remaining from those that entered the society at the age of 17, makes 4, coming under observation at some time or other after completing the 17th year of their life, and before completing the 18th year; none of these become subject to any of the events specified, and the whole 4 are therefore carried under observation to the following age, 19, when 2 other officers entered the society, making 6 under observation at the age of 19. Again, at age 25, 168 officers entered the society, who, with 484 remaining under observation from the preceding age, make altogether 652 under observation at the age of 25. Of these, 26 die during the course of that year, 15 are struck off, and 12 discontinue, while 25, who have recently entered the society, remain alive on the 1st of January, 1851, and, therefore, are no longer observed; 78 officers, in all, therefore, go from under observation at the age of 25, and 574 are carried forward to the succeeding age of 26, which, with 133 entered at that age, brings 707 officers altogether under review at the age of 26.

(*e*) Represents the numbers dying at each age or term of life.

(*f*) Those who are struck off.

(*g*) Those who discontinue.

(*h*) Represents the number of officers alive on the 1st of January, 1851, and who have not become subject to any of the contingent events represented in columns *e* to *g* inclusive.

(*i*) Contains the total of columns *e* to *h*, inclusive, and represents the number of officers who cease to come under observation in any of the more advanced ages. For example, at the age 30, column *d* represents 570 under observation; but before attaining the 31st year of age, 57 of these pass from observation, leaving 513 to come under observation in the 31st year of age, as shewn in column *c*.

(*j*) Represents one-half of the numbers entering the society at each year of life at which admissions take place, and is, therefore, one-half of the numbers in column *b*. In like manner, column

(*k*) Represents one-half of the numbers in column *f*. In like manner, column

(*l*) Represents one-half the numbers in column *g*; and column

(*m*) The total of columns *j*, *k*, and *l*. The purpose of these four columns will appear in the explanation of column

(*n*) Which represents the number of lives exposed a complete year to the risk of mortality while connected with the society, and the figures in this column are produced by subtracting from the numbers in column *d* the numbers in column *m* opposite the same age. As already stated, column *d* contains the gross number under observation at some time or other throughout the year of life set forth in column *a*; but as column *b* contains, for each age up to 66, the numbers who have entered the society, and as officers, one with another, enter at different periods throughout the year, it has been found, by observation, that on an average each is, during the year of entry, exposed to only six months, or one half-year's mortality, and hence column *j* represents that amount of risk for all officers who have just joined the society. In like manner columns *k* and *l* represent the amount of risk to which officers discontinued from the society for either of the causes specified in those columns, are exposed, on the principle that, one with another, the discontinuances will take place in the middle of the year. It thus appears that as column *m* is the total of *j*, *k*, and *l*, it shews the proper number to be deducted from column *d*, in order to find the number exposed to the risk of a whole year's mortality.

The following Abstract, A, will make the contents of the preceding Table better understood.

ABSTRACT A.

| Ages.      | Number Exposed to Risk. | Died. | Mortality per Cent. |
|------------|-------------------------|-------|---------------------|
| 20 to 24   | 1016.5                  | 51    | 5.017               |
| 25 ... 29  | 3005.0                  | 88    | 2.928               |
| 30 ... 34  | 2498.0                  | 60    | 2.402               |
| 35 ... 39  | 2064.0                  | 41    | 1.986               |
| 40 ... 44  | 1764.5                  | 44    | 2.494               |
| 45 ... 49  | 1447.0                  | 24    | 1.660               |
| 50 ... 54  | 1124.5                  | 27    | 2.401               |
| 55 ... 59  | 833.5                   | 19    | 2.280               |
| 60 ... 64  | 483.5                   | 12    | 2.482               |
| 65 ... 69  | 259.0                   | 8     | 3.089               |
| 70 ... 74  | 123.0                   | 8     | 6.504               |
| 75 ... 79  | 42.5                    | 3     | 7.059               |
| 80 ... 84  | 4.0                     | 1     | 25.000              |
| Total..... | 14665.0                 | 386   | 2.632               |

It is thus seen that during 14,665 years of risk, to which the members whose experience is recorded in Table I were exposed, no less than 386 died, or 2.632 per cent., while the mortality according to the average for the whole male population of England and Wales at corresponding ages is 1.888 per cent. But what is most striking about these results is the very excessive mortality at the ages under 55, and the reduced mortality at the ages 55 and upwards. This will be found to exceed not only the mortality of the male population of England and Wales at the mature and active term of life, but to be actually about equal to that of the officers of the Bengal military service at the corresponding ages. The following exhibits the results for each of the three classes:—

Mortality in the term of life, 20–54 among

The Members of the Medical Department of the Army = 2.593 per cent.

The Officers of the Bengal Army . . . . . = 2.635 ...

The Male Population of England and Wales . . . . . = 1.155 ...

It is thus evident that the rate of mortality among the members of the medical department of the army, who entered the Society while unmarried, does not differ widely

from that found to prevail among the officers of the Bengal army ; but at the same time it will be found to exceed the rate of mortality among the male population of this country by 124·502 per cent. This very striking and unexpected result at once proved the necessity for an accurate analysis of the rate of mortality among the members of the Society.

In the preceding Abstract A, there is one feature which cannot fail to arrest attention : the remarkably high and unprecedented mortality at the younger ages, which gradually decreases up to the age of 40. The following shews the mortality per cent. for each quinquennium in the three preceding groups of observations :—

| Ages.     | Medical Department of the Royal Army. | Bengal Military Fund. | Male Population of England and Wales. |
|-----------|---------------------------------------|-----------------------|---------------------------------------|
| 20 to 24  | 5·017                                 | 2·324                 | 0·845                                 |
| 25 ... 29 | 2·928                                 | 2·501                 | 0·981                                 |
| 30 ... 34 | 2·402                                 | 2·779                 | 1·049                                 |
| 35 ... 39 | 1·986                                 | 2·864                 | 1·134                                 |

The mortality at the younger ages in the medical department of the army is certainly a circumstance of much importance; and on more grounds than one, calls for investigation and inquiry : but in order to shew how very diversified is the rate of mortality in individual classes of the community, it may be well to direct attention to the remarkable contrasts in the results of the three preceding groups, at ages 55 and upwards, or rather within the term of life, 55–84.

The rate of mortality in each of the following classes in the term of life 55–84 :

Members of the Medical Department of the Royal Army = 2·922 per cent.

Officers of the Bengal Army . . . . . = 5·652 ...

Male Population of England and Wales . . . . . = 5·056 ...

The very low rate of mortality at the advanced ages among the members of the medical department of the army, as set forth in Abstract A, is just as remarkable as the excessive rate found to prevail at the younger ages.

So much having been said on the rate of mortality among those members who entered the Society while single or unmarried, attention will next be directed to those who joined the Society as married members.

The explanation already given of the construction of Table I will be equally applicable to the following Table, and, therefore, need not be repeated.

[The following

TABLE II.

*Mortality of those who entered Married.*

| Age. | Number Entered<br>at each Age. | Number remain-<br>ing under Ob-<br>servation from<br>Age preceding. | Total Number<br>under Observa-<br>tion at each<br>Age. | Died. | Struck off. | Discontinued. | Alive. | Total gone off. | Half of  |             |                    |        | Number<br>Exposed<br>to Risk. |

The following Abstract will make the contents of Table II better understood.

ABSTRACT B.

| Ages.       | Number Exposed to Risk. | Died. | Mortality per Cent. |
|-------------|-------------------------|-------|---------------------|
| 25 to 29    | 84.0                    | 1     | 1.190               |
| 30 ... 34   | 253.5                   | 1     | .395                |
| 35 ... 39   | 451.5                   | 9     | 1.993               |
| 40 ... 44   | 589.5                   | 11    | 1.866               |
| 45 ... 49   | 682.0                   | 10    | 1.466               |
| 50 ... 54   | 663.5                   | 19    | 2.863               |
| 55 ... 59   | 566.5                   | 21    | 3.823               |
| 60 ... 64   | 428.5                   | 14    | 3.267               |
| 65 ... 69   | 311.5                   | 11    | 3.531               |
| 70 ... 74   | 159.5                   | 12    | 7.524               |
| 75 ... 79   | 83.5                    | 9     | 10.778              |
| 80 ... 84   | 11.0                    | 2     | 18.181              |
| Total ..... | 4284.5                  | 120   | 2.801               |

It is thus found that while the collected results for the preceding Abstract shew a somewhat higher mortality than that in Abstract A, there is still a great dissimilarity at the different periods of life. The mortality, as given in Abstract B, which represents the deaths among such members as entered the Society when married, being more in accordance with the results derived from observations on other classes of society, exhibiting an increasing rate of mortality as life advances, and pretty uniformly exceeding that for England and Wales; the few irregularities may be fairly supposed to arise from the fluctuations due to the comparatively small number of facts over which the observations recorded in Abstract B extend.

In order to compare the results in this Abstract with those already furnished in Abstract A, it will be sufficient to give the rate of mortality within the periods of 25-54 and 55-84.

| Ages.     | Mortality per Cent. among those Members who entered the Society |                      |
|-----------|-----------------------------------------------------------------|----------------------|
|           | Unmarried, Abstract A.                                          | Married, Abstract B. |
| 25 to 54  | 2.386                                                           | 1.872                |
| 55 ... 84 | 2.922                                                           | 4.422                |

This Abstract affords abundant evidence in support of the conclusion that there is some circumstance connected with the mode or condition of life in which the members of the two classes were placed, having a marked influence on their health and longevity. It is, however, unnecessary to dwell longer on the difference between the preceding two classes, for it is obvious that, in Abstract A, which includes the group entering the Society while unmarried, many of them must have married subsequent to the date of entry, and therefore the results do not afford a proper comparison between the mortality incidental to the conditions of married and single life; another analysis has, therefore, been made to shew the results peculiar to those conditions.

[The first

TABLE III.

*Mortality among Members entering Single, and remaining under Observation whilst Single only.*

| Age. | Number Entered at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Died. | Struck off. | Discontinued. | Married. | Alive. | Total gone off. | Half of  |             |               |          | Total. | Number Exposed to Risk. |
|------|-----------------------------|--------------------------------------------------------|---------------------------------------------|-------|-------------|---------------|----------|--------|-----------------|----------|-------------|---------------|----------|--------|-------------------------|
|      |                             |                                                        |                                             |       |             |               |          |        |                 | Entered. | Struck off. | Discontinued. | Married. |        |                         |

| 85   | ..                          | ..                                                     | ..                                          | ..    | ..          | ..            | ..       | ..     | ..              | ..       | ..          | ..            | ..       | ..     | ..                      |
|      | 1,340                       | ..                                                     | 12,113                                      | 304   | 165         | 228           | 249      | 394    | 1,340           | 670.0    | 82.5        | 114.0         | 124.5    | 991.0  | 11139.0                 |

The first part of the inquiry, made to shew the results connected with the mortality of single life, will be found set forth in the preceding Table, which contains all the facts bearing on the rate of mortality among such members as entered the Society in the single condition, and the observations extending over the period while they remained single. In the event of any member becoming married, all further observation ceases.

The following Abstract C, shews the results arrived at in Table III.

ABSTRACT C.

| Ages.     | Number Exposed to Risk. | Died. | Mortality per Cent. |
|-----------|-------------------------|-------|---------------------|
| 20 to 24  | 1011.0                  | 51    | 5.045               |
| 25 ... 29 | 2905.0                  | 85    | 2.926               |
| 30 ... 34 | 2150.5                  | 55    | 2.558               |
| 35 ... 39 | 1543.0                  | 33    | 2.138               |
| 40 ... 44 | 1162.0                  | 36    | 3.099               |
| 45 ... 49 | 858.0                   | 11    | 1.282               |
| 50 ... 54 | 601.5                   | 16    | 2.660               |
| 55 ... 59 | 393.5                   | 7     | 1.779               |
| 60 ... 64 | 234.0                   | 3     | 1.282               |
| 65 ... 69 | 138.0                   | 2     | 1.449               |
| 70 ... 74 | 81.5                    | 3     | 3.681               |
| 75 ... 79 | 31.0                    | 2     | 6.451               |
| 80 ... 84 | 3.0                     | ...   | ...                 |
| Total...  | 11112.0                 | 304   | 2.736               |

This Abstract shews that the results characteristic of Abstract A are still more strongly developed here; the mortality of early life being higher, that of advanced life lower, and the general mortality even being higher than that of Abstract A. It would hence follow that the elimination of the cases of those who subsequently married has the effect of increasing the general mortality for the residue, as well as increasing the mortality at the early ages and diminishing it at the advanced periods of life. This will be more clearly seen by an inspection of the following figures:—

| Ages.     | Mortality per Cent.<br>among all those who entered<br>Single.<br>Abstract A. | Mortality per Cent.<br>of those who entered<br>Single,<br>but were excluded from<br>further observation after<br>becoming Married.<br>Abstract C. |
|-----------|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 20 to 54  | 2.593                                                                        | 2.805                                                                                                                                             |
| 55 ... 84 | 2.922                                                                        | 1.918                                                                                                                                             |
| 20 ... 84 | 2.632                                                                        | 2.736                                                                                                                                             |

It is hence evident that the vicissitudes of unmarried life have a more powerful influence on mortality under the age of 55 than above it, compared with the causes connected with the married condition; and further evidence of this will be derived from the following two Abstracts.

In the next Abstract are included such facts only as constitute the complement of Table III, that is, the observations connected with those who have entered the Society while single, but who afterwards married,—the observations commencing from the date of marriage; and therefore the facts in Table III and the following Abstract, constitute the whole of those given in Table I. It has already been shewn that the aggregate mortality of Table III exceeds that of Table I, and therefore the mortality of the next Abstract must fall under that of Table I; but it has also been shewn that the mortality of Table III has, in an eminent degree, portrayed the features characteristic of Table I, and, consequently, Abstract D, following, must be expected to be more uniform, and approximate more nearly to the rate of mortality prevailing in Table II.

#### ABSTRACT D.

*Mortality of those who entered Single, but afterwards Married; the observations commencing at Marriage.*

| Ages.     | Number Exposed to Risk. | Died. | Mortality per Cent. |
|-----------|-------------------------|-------|---------------------|
| 20 to 24  | 5.5                     | ...   | ...                 |
| 25 ... 29 | 100.0                   | 3     | 3.000               |
| 30 ... 34 | 347.5                   | 5     | 1.439               |
| 35 ... 39 | 521.0                   | 8     | 1.536               |
| 40 ... 44 | 602.5                   | 3     | 1.328               |
| 45 ... 49 | 589.0                   | 13    | 2.207               |
| 50 ... 54 | 523.0                   | 11    | 2.103               |
| 55 ... 59 | 440.0                   | 12    | 2.727               |
| 60 ... 64 | 249.5                   | 9     | 3.607               |
| 65 ... 69 | 121.0                   | 6     | 4.959               |
| 70 ... 74 | 41.5                    | 5     | 12.048              |
| 75 ... 79 | 11.5                    | 1     | 8.070               |
| 80 ... 84 | 1.0                     | 1     | 100.000             |
| Total...  | 3553.3                  | 82    | 2.308               |

The following shews the condensed results of this Abstract:—

Mortality from ages 20 to 54 = 1.785 per cent.

... .. 55 ... 84 = 3.944 ...

... .. 20 ... 84 = 2.308 ...

Table III, preceding, shewed the rate of mortality among such members as entered single, during the period they continued so, all further observations ceasing after marriage. In the next Abstract will be set forth the rate of mortality among the married members; and it will embrace all the facts of those who entered married, as given in Table II, as well as of those who entered single but afterwards married, the observations commencing at the date of marriage, the facts of which are contained in Abstract D.

#### ABSTRACT E.

*Mortality among Members entered Married, and entered Single but afterwards Married; the Single coming under observation at Marriage.*

| Ages.     | Number Exposed to Risk. | Died. | Mortality per Cent. |
|-----------|-------------------------|-------|---------------------|
| 25 to 29  | 184.0                   | 4     | 2.174               |
| 30 ... 34 | 601.0                   | 6     | .998                |
| 35 ... 39 | 972.5                   | 17    | 1.748               |
| 40 ... 44 | 1192.0                  | 19    | 1.594               |
| 45 ... 49 | 1271.0                  | 23    | 1.810               |
| 50 ... 54 | 1186.5                  | 30    | 2.529               |
| 55 ... 59 | 1006.5                  | 33    | 3.279               |
| 60 ... 64 | 678.0                   | 23    | 3.392               |
| 65 ... 69 | 432.5                   | 17    | 3.931               |
| 70 ... 74 | 201.0                   | 17    | 8.458               |
| 75 ... 79 | 95.0                    | 10    | 10.526              |
| 80 ... 84 | 12.0                    | 3     | 25.000              |
| Total ... | 7832.0                  | 202   | 2.580               |

In this Abstract the following will be found to represent the general results arrived at:—

Mortality from ages 25—54 = 1.831 per cent.

... .. 55—84 = 4.247 ...

... .. 25—84 = 2.580 ...

The results of this Abstract, as compared with those of Table III and Abstract C, are interesting, as shewing the distinction between the mortality of married and single life. The following gives a condensed illustration of the difference of mortality:—

| Ages.     | Mortality per Cent. among the Married and Single Members of the Society. |                                 |
|-----------|--------------------------------------------------------------------------|---------------------------------|
|           | Single Members.<br>Abstract C.                                           | Married Members.<br>Abstract E. |
| 25 to 54  | 2.559                                                                    | 1.831                           |
| 55 ... 84 | 1.918                                                                    | 4.247                           |
| 25 ... 84 | 2.504                                                                    | 2.580                           |

In this, as in the preceding instances, it is obvious that the characteristic of the mortality of single life is still maintained, the rate of mortality among the unmarried members being greater at the earlier ages, and less at those ages more advanced.

Having thus exhibited the rate of mortality for each of the preceding groups and combinations, it may be now useful to shew the results for the combined experience of all the members, whether married or single. The following Abstract F shews, for each quinquennial term of life, the rate of mortality among all the members of the Society from its establishment in 1816, till the 1st of January, 1851.

## ABSTRACT F.

*Mortality among all the Members, Married and Single.*

| Ages.     | Number Exposed to Risk. | Died. | Mortality per Cent. |
|-----------|-------------------------|-------|---------------------|
| 20 to 24  | 1016.5                  | 51    | 5.017               |
| 25 ... 29 | 3089.0                  | 89    | 2.881               |
| 30 ... 34 | 2751.5                  | 61    | 2.217               |
| 35 ... 39 | 2515.5                  | 50    | 1.988               |
| 40 ... 44 | 2354.0                  | 55    | 2.336               |
| 45 ... 49 | 2129.0                  | 34    | 1.597               |
| 50 ... 54 | 1788.0                  | 46    | 2.573               |
| 55 ... 59 | 1400.0                  | 40    | 2.857               |
| 60 ... 64 | 912.0                   | 26    | 2.850               |
| 65 ... 69 | 570.5                   | 19    | 3.330               |
| 70 ... 74 | 282.5                   | 20    | 7.080               |
| 75 ... 79 | 126.0                   | 12    | 9.524               |
| 80 ... 84 | 15.0                    | 3     | 20.000              |
| Total...  | 18949.5                 | 506   | 2.670               |

The condensed results are as follows:—

Mortality between ages 20 to 54 = 2.467 per cent.

... 55 ... 84 = 3.629 ...

... 20 ... 84 = 2.670 ...

The next Abstract will give a succinct view of the results set forth in each of the preceding six Abstracts, as well as the general mortality at the corresponding ages for the male population of England and Wales, as given in the earlier part of this Volume, pages 4 and 6.

## ABSTRACT G.

| Ages.     | Mortality per Cent.   |                        |                                                                     |                                                                                        |                                                                                                |                                            | Male Population of England and Wales. |

| Male population of England and Wales.....               | 1.166                       | 5.056       | 1.918       |

As already stated, each Abstract gives the data and correct rate of mortality for each quinquennial period of life; and the above condensed form of exhibiting the mortality per cent. may, for general purposes, be considered sufficient to illustrate the relative bearing of the different groups; but, at the same time, it is necessary to exercise caution against the employment of those figures or others similarly derived, and extending over any considerable term of life, as giving an exact expression of the true mortality among the different classes compared. The true mortality can only be collected from the details

of each of the preceding Tables, or from the rate of mortality given for each quinquennium in the corresponding Abstracts A, B, C, D, E, and F. The nature of the error contained in the condensed illustrations will be found explained in page 44 *ante*. The conditions necessary to the correct comparison of results derived from observations extending over a considerable term of life, such as between ages 25-54, 55-84, and 25-84, or any other extended periods of life are, that the relative numbers of persons over which the observations are made at the different periods of life should be in exact proportion to each other in the different groups of observations; but should there be in any one group an undue proportion of persons at the younger or older ages, the resulting rate of mortality will become modified accordingly, even although out of equal numbers in each group at different ages the same number of deaths would take place in the same time. Inattention to the errors inherent in such illustrations has often led inquirers to very false conclusions; the method is, however, useful, if employed only for general purposes, and with proper caution. The following figures exhibit the number of years' risk observed on at each term of life.

| GROUPS.                                                         | Number of Years' Observation at the Term of Life. |                      |           |                      |

| ... F.—Both single and married members .....                    | 14627·0                                           | 81·6                 | 3306·0    | 18·4                 |

It is evident that in some of the above groups there is very great irregularity in the distribution of the number of facts, or years of risk observed at different ages, and hence the rate of mortality per cent. derived from these collected or aggravated results, and which must necessarily be a mean of such irregularly distributed facts, cannot be relied on as shewing the correct relation of the causes of mortality pressing on each class of observations. These remarks apply with greater force to the comparison of the results for the aggregate of all ages, than to the comparative results for either of the extended terms of life, 25-54, or 55-84. It will be seen that in Group C, 91·3 per cent. of the facts are contained between ages 25-54, but in Group B there is only 63·5 per cent. of the observations of that group made between the same ages.

There is another method, however, by which the aggregate mortality of the combined ages may be compared without any error, and that is by comparing the actual number of deaths which has taken place, in each class or group, with that which would have taken place if the rate of mortality had prevailed at each term of life in each group,

which is known to correctly represent the mortality at the same terms of life in any given standard table of mortality with which the results of each group may be compared.

The following shews the number of deaths which have actually taken place in each group, and the number which would have taken place had the same rate of mortality prevailed which is known to represent the mortality of the male population of this country.

## ABSTRACT H.

| Groups.     |                                                        | Difference between the Mortality which has actually taken place and that which would have happened, according to the ratio for the Male Population of England and Wales, between the following Ages : |                    |                      |         |                    |                      |         |                    |                      |

| „           | F. Both Married and Single }<br>Members .....          | 386                                                                                                                                                                                                   | 190·3              | + 113                | 120     | 121·6              | — 1                  | 506     | 211·9              | + 62                 |

An examination of the above results only confirms the conclusions formerly arrived at; namely, that the members taken in the aggregate under the age of 55 are subject to an unprecedented amount of mortality, but that subsequent to that age the rate of mortality does not differ widely from that of the population generally: as may be more apparent from the following figures taken from the preceding abstract:—

|                                              | Actual. | England and Wales. |
|----------------------------------------------|---------|--------------------|
| Number of deaths between the ages 20 to 54 = | 386     | 190·3              |
| ... .. 55 ... 84 =                           | 120     | 121·6              |
| ... .. 20 ... 84 =                           | 506     | 311·9              |

It is also evident, from the results of the preceding abstract, as well as from those formerly brought under consideration, that the mortality in Group E, which represents the married members, differs very widely from that in Group C, which represents the unmarried.

| Period of Life.    | Difference per Cent. between the Actual Mortality and that of England and Wales among the |                |
|--------------------|-------------------------------------------------------------------------------------------|----------------|
|                    | Unmarried Group.                                                                          | Married Group. |
| Between Ages 20—54 | + 147 per Cent.                                                                           | + 33 per Cent. |
| ... .. 55—84       | — 47 ...                                                                                  | + 15 ...       |
| ... .. 20—84       | + 101 ...                                                                                 | + 24 ...       |

It is thus abundantly evident that the rate of mortality of the married members is so very different from that of the single, that in any calculations intended to measure the duration of life among the married members only, it would not be proper to include the mortality of the single members.

The following Table is formed from the data given in Abstract E, preceding, and represents the mortality for the mean of each quinquennial term of life among the married members of the Society. For a detailed explanation of the principles on which Tables IV and V are constructed, see the subsequent portion of these contributions on the mortality among persons of intemperate habits.

TABLE IV.

|      |                                                          |                                                                                            |                              |                  | 101  |                                                          | 1.27142                                                                                    | 19                           | 7                |

An examination of the results set forth in column 4 of this Table shews that of the number living at age 25, one-half only will be alive in about thirty-four years afterwards, but in the male population of England and Wales one-half would be alive for forty years afterwards. The following shews the equation of life in the above Table, which represents the mortality of the married members of the Society, and also according to the mortality of the male population of England and Wales.

| Ages. | Equation of Life among the                      |                              |
|-------|-------------------------------------------------|------------------------------|
|       | Married Members<br>of the Society.<br>Table VI. | Males.<br>England and Wales. |
| 25    | 34.525                                          | 40.309                       |
| 30    | 32.453                                          | 36.482                       |
| 40    | 26.772                                          | 28.790                       |
| 50    | 20.169                                          | 21.255                       |

The next portion of this paper relates to the rate of mortality among the members of the Royal Medical Chirurgical Society, deduced from a list which was furnished to me of all the resident members elected into the Society since its establishment in the year 1805, specifying the date of election, the causes of withdrawal or removal from the Society, or whether they still continue members. This list has been analysed so as to exhibit, in a clear and simple manner, the rate of mortality among the members.

In the first place attention is directed to Table VII, which furnishes a very interesting and succinct view of the changes of the Society, in respect to the election and withdrawal of its members for each year since the commencement. From the second column of this Table it will be seen that, since the year 1805, 684 resident members have been elected, and, by column 5, 96 of these have died, and, according to column 6, 280 have either resigned or, from some cause or other, have ceased to be resident members, so that out of the whole 684 members elected, 376 have now, from various causes, ceased to belong to the Society, leaving, at the period up to which the abstracts were completed, 308 existing members. The other columns of the Table explain themselves, but the point to which attention is now specially directed is that of the rate of mortality amongst the members. The last column shews the rate of mortality, but Abstract I gives a more condensed and convenient view of the results arrived at:—

TABLE VII.

| Year of Entry. | Number Entered. | Number under Observation from Year preceding. | Total Number under Observation in each Year. | Died. | Resigned, Ceased to Pay, and Ejected. | Total gone off. | Half of  |               |        | Number Exposed to Risk of Mortality. | Mortality per Cent. |
|----------------|-----------------|-----------------------------------------------|----------------------------------------------|-------|---------------------------------------|-----------------|----------|---------------|--------|--------------------------------------|---------------------|
| (1)            | (2)             | (3)                                           | (4)                                          | (5)   | (6)                                   | (7)             | Entered. | Discontinued. | Total. | (11)                                 | (12)                |

## ABSTRACT I.

| Years.        | Number Exposed to Risk. | Died. | Mortality per Cent. |
|---------------|-------------------------|-------|---------------------|
| 1805 to 1809  | 303.0                   | 1     | 0.330               |
| 1810 ... 1814 | 410.5                   | ...   | 0.000               |
| 1815 ... 1819 | 710.0                   | 3     | 0.423               |
| 1820 ... 1824 | 926.6                   | 5     | 0.539               |
| 1825 ... 1829 | 950.0                   | 17    | 1.789               |
| 1830 ... 1834 | 795.5                   | 21    | 2.639               |
| 1835 ... 1839 | 933.0                   | 9     | 0.965               |
| 1840 ... 1844 | 1278.5                  | 14    | 1.095               |
| 1845 ... 1849 | 1527.5                  | 26    | 1.702               |
| Total.....    | 7834.0                  | 96    | 1.225               |

So far as these results extend, and considering the limits within which the ages of the members, on admission, must range, it is evident that the mortality of the members is under that of the population of the country generally.

Attention is next requested to Table VIII, which very much resembles Table VII, only that the final column exhibits the ratio of withdrawals from all causes, inclusive of deaths, for each year of the Society's existence. From the following condensed Abstract of this Table, it will be seen that, with the exception of the first quinquennial period of years, there is no very extraordinary fluctuation in the ratio of withdrawals from the general average.

## ABSTRACT J.

| Year of Entry. | Number Exposed to Risk of Withdrawal. | Total gone off. | Per Centage of Total Withdrawals. |
|----------------|---------------------------------------|-----------------|-----------------------------------|
| 1805 to 1809   | 304.0                                 | 3               | 0.987                             |
| 1810 ... 1814  | 421.5                                 | 22              | 5.219                             |
| 1815 ... 1819  | 721.5                                 | 26              | 3.604                             |
| 1820 ... 1824  | 944.5                                 | 42              | 4.447                             |
| 1825 ... 1829  | 967.5                                 | 52              | 5.375                             |
| 1830 ... 1834  | 816.5                                 | 63              | 7.716                             |
| 1835 ... 1839  | 942.0                                 | 27              | 2.866                             |
| 1840 ... 1844  | 1295.5                                | 48              | 3.705                             |
| 1845 ... 1849  | 1561.0                                | 93              | 5.951                             |
| Total.....     | 7974.0                                | 376             | 4.715                             |

It is obvious, however, that Tables VII and VIII give, simply, a chronological view of the Society since its commencement, exhibiting the changes which have taken place in its members during each particular year. It is, however, evident that the more important aspect in which to look at the question is the ratio of withdrawals from the Society, from various causes, during the first, second, and each succeeding year of membership, without regard to the chronological dates of these events. Table IX has, therefore, been constructed [on this

TABLE VIII.

| Year of Entry. | Number Entered | Number under Observation from Year preceding. | Total Number under Observation in each Year. | Died. | Resigned, Ceased to Pay, and Ejected. | Total gone off. | Half of Entered. | Number Exposed to Risk of Withdrawal from the Society from all causes, including Death. | Per Centage of Total Withdrawals. |
|----------------|----------------|-----------------------------------------------|----------------------------------------------|-------|---------------------------------------|-----------------|------------------|-----------------------------------------------------------------------------------------|-----------------------------------|
| (1)            | (2)            | (3)                                           | (4)                                          | (5)   | (6)                                   | (7)             | (8)              | (9)                                                                                     | (10)                              |
| 1805           | 60             | ...                                           | 60                                           | ...   | ...                                   | ...             | 30               | 30                                                                                      | 0.987                             |
| 1806           | 7              | 60                                            | 67                                           | ...   | ...                                   | ...             | 3.5              | 63.5                                                                                    |                                   |
| 1807           | 2              | 67                                            | 69                                           | ...   | ...                                   | 3               | 1                | 68                                                                                      |                                   |
| 1808           | 3              | 69                                            | 72                                           | ...   | 1                                     | 1               | 1.5              | 70.5                                                                                    |                                   |

|                             | 8,316                                              | 96    | 280                                                             | 308    | 684                | 140.0                            | 7834.0                                        | 1.225                  |

on this hypothesis; the first column shews the years of membership, the second column shews the number of members who have been one, two, three, four, &c., years connected with the Society, and the other columns sufficiently explain themselves. It thus appears that of the 684 members elected, *one* died in the first year of membership, and 15 still remain alive, being in the first year of membership. Again, 668 entered on the second year of membership, two died in that year, 10 withdrew from other causes, and 22 are alive who are members of not more than two years' standing. Also four entered on the forty-second year of their membership, one died in that year, and one of them remains alive, being a member of forty-two years' standing. Likewise of the two members who entered on the forty-third year of membership, one died in that year, and the other passed on to the forty-fourth year of membership, and died. It hence appears that the whole 684 members elected have, up to the present time, passed through 8,316 years of observation, or about 12 years to each member; but this must not be confounded with the average period of membership, for the above result is derived from observations on a large number but recently elected; the correct average duration of membership will hereafter appear. The average rate of mortality in this Table will be found to coincide with that of Table VII being 1.225 per cent., but an inspection of the last column shews that as the period of membership increases, or, in other words, as age advances, there is a marked increase in the rate of mortality. The following is a brief Abstract of the results in Table IX.

ABSTRACT K.

| Years in the Society. | Number Exposed to Risk of Mortality. | Died. | Mortality per Cent. |
|-----------------------|--------------------------------------|-------|---------------------|
| 1 to 4                | 2198                                 | 9     | 0.409               |
| 5 ... 9               | 2190.5                               | 14    | 0.639               |
| 10 ... 14             | 1353.5                               | 20    | 1.477               |
| 15 ... 19             | 811.5                                | 11    | 1.355               |
| 20 ... 24             | 578.5                                | 8     | 1.383               |
| 25 ... 29             | 410                                  | 17    | 4.146               |
| 30 ... 34             | 200                                  | 7     | 3.500               |
| 35 ... 39             | 74                                   | 6     | 8.108               |
| 40 ... 44             | 18                                   | 4     | 22.222              |
| Total,.....           | 7834                                 | 96    | 1.225               |

Assuming that the average age of admission of members will range from 25 to 35 years of age, although, perhaps, it may be more strictly stated to range between 25 and 30, an inspection of the above figures will shew that at the younger ages the mortality is much less than the average of the population generally, but at the older and more advanced ages greater.

The next Table, X, is similar in arrangement to Table IX, only shewing in the final column, instead of the rate of mortality, the ratio per cent., as in Table VIII, of withdrawals from the Society from all causes, including death, and here, as in the preceding Table, the causes of withdrawal will be found to increase with the period of membership.

From the results of this Abstract, Table XI has been constructed so as to exhibit in an interesting manner the average duration of membership as deduced from the experience of the Royal Medical Chirurgical Society, from its establishment, in the year 1805, up to the present time.

This Table has been constructed from the results set forth in the last column of Abstract L, in the same manner in which Table VI, preceding, was constructed from the figures given in Abstract E, only that, in the former case, third differences were used in the interpolations, but in the later instances, second differences only, see the subsequent portion of these contributions on the Mortality of Master Mariners.

Assuming that 100,000 members, or any submultiple by ten of that number, entered the Society, column 4 will shew the numbers remaining in the Society in each succeeding year, and column 5 will shew the number of members withdrawing from all causes. Hence, of 100,000 members, 1920 would withdraw in the first year of membership, or of 1000 entering, 19 would withdraw. Again, of 1000 members elected into the Society, 516 would enter on the fifteenth year of membership, and 486 on their sixteenth year, or, in other words, the equation of membership, or what is technically of almost the same value for the present purpose, the expectation of membership when just elected is about fifteen and a half years. If the experience of this Society can be taken as any criterion of that of other learned societies, this result deduced from the preceding Table would be of some practical importance in the regulation of the composition-money required in lieu of the annual subscriptions paid by members. Keeping in view the fact that the expectation of membership is about fifteen years, it is easy to determine the present value of a corresponding annuity. By the term "present value," is meant the single sum of money [which paid

TABLE XI.

which paid down, would, if invested at the same rate of interest as the annual subscriptions, meet precisely the same liabilities as they fall due. Assuming that the funds or composition paid in commutation of yearly subscriptions could be invested to yield 3 per cent. compound interest, the present value of the annuity equivalent to that dependent on the expectation of membership is about eleven years' purchase. But there is another view to be taken of this question. If the practice of receiving composition payments were permitted and generally adopted by the members, there can be no doubt that the withdrawals from the Society from other causes than death, or those specified in column 4 of Table D, would be very much reduced. Different societies will, no doubt, be variously affected by these causes, and this feature of Tables VII, VIII, IX, and X, has been introduced here principally in order to direct more general attention to the question.

It is, however, very curious and instructive to observe the rate of mortality developed in some of these latter Tables, and particularly in Table IX and Abstract K, as compared with the rate of mortality found to prevail among the medical officers of the Royal Army. The difference is certainly one of the most remarkable results yet deduced by any inquiry into Vital Statistics.

The following Abstract M shews that throughout the period of life 26-70, the mortality among the members of the Royal Medical and Chirurgical Society approximates very closely to that of the male population of England and Wales, being considerably less between ages 26-35, somewhat higher above 35 years of age, but in the whole term of life, varying from 26 to 70 years of age, the mortality differs but little: the actual number of deaths in the Society being 96, while that which would have taken place according to the mortality of England and Wales is 97·1.

#### ABSTRACT M.

##### *Mortality among the Members of the Royal Medical and Chirurgical Society.*

| Age.      | Number Exposed to Risk. | Mortality per Cent. | Deaths.               |        | England and Wales.  |                                                       |        |

In vol. ix. of the Journal of this Society will be found an interesting paper by Dr. Guy, "On the Duration of Life in several Professions," distinguishing, among others, the Medical Profession. The results arrived at by Dr. Guy shew a somewhat greater mortality than that for the male population generally of this country. In vol. xvii. of the same Journal will be found another paper by Dr. Guy, "On the Duration of Life among Medical Men," founded on a larger body of facts. The results of his second inquiry however agree closely with those of the first, considering the nature of the data and the mode of investigation followed. There is also before the public the well-known body of facts collected by Professor Casper, of Berlin, and which exhibits a higher rate of mortality than even the results of Dr. Guy's paper; but it is only right to bear in mind that, however valuable these contributions may be considered, both collections of facts are defective in one very important element, namely, the number of medical men in the profession or class in which the deaths are recorded. Neither Dr. Guy nor Professor Casper had the means of ascertaining the amount of population in the respective groups in which the deaths recorded took place; but, under the circumstances, they have made the best possible use of the materials at their command. In the facts brought forward in this paper, however, it will be seen that the number of the living, both in the officers of the Medical Department of the Royal Army and among the members of the Royal Medical Chirurgical Society, is known, and therefore all the elements necessary to a complete inquiry into the duration of life in each of these classes are available. It could also be easily shewn that the effect of introducing the wanting element in Dr. Guy's inquiry would be to increase the duration of life assigned to the results he has arrived at, and thereby make the rate of mortality approximate more closely to those set forth in Abstracts K and M, preceding.

It is very satisfactory to find so near an agreement in the results of two independent inquiries, originating in so different a manner, and resting on so very different sources of information. But this coincidence only makes the results of the investigation into the duration of life among the officers of the Medical Department of the Army, as brought forward in the early part of this paper, the more remarkable and extraordinary.

It will be observed, that although a very complete analysis has been made of the social condition of life of the medical officers of the Royal Army, in order to arrive at the rate of mortality peculiar to those conditions, still no attempt has been made to determine the physical causes which it is evident prevail so powerfully in producing differences of mortality of so striking a nature as to be wholly without precedent in all former inquiries in the diversified field of Vital Statistics. It is proposed to reserve this more generally interesting part of the investigation for a future occasion.

It may, however, be now stated that the very high rate of mortality under the age of 54, but more particularly under the age of 40, as indicated by the results in all the Abstracts from A to F inclusive, had, in the first place, been supposed to arise from the

younger medical officers being probably sent to unhealthy stations. In order to test the merits of this hypothesis, an examination was permitted to be made of the records at the War-office, to determine the place of death; but of the 506 deaths given in Tables I and II, the place was found specified for only 308, and the following is a condensed Abstract of the results of this part of the inquiry.

### ABSTRACT N.

*Places at which 308 Members of the Royal Army Medical Fund have died, distinguishing the Age at time of Death.*

| Place of Death.           | Age at Death. |          |          |          |          |          |          |          |          |          |          |          |          | Total.     |            |            |

An inspection of the figures in this Abstract, will at once shew that the number of deaths which has taken place in unhealthy colonies, is not sufficient to account for the unprecedented amount of mortality under age 40. If the whole of the deaths in the three last groups of the preceding Abstract were excluded, the mortality assigned to the first and second groups would still be greatly in excess of that which under ordinary circumstances is experienced in this country, and other equally healthy places; in fact,

under the age of 35, the rate of mortality would, even after the elimination of the second section of Abstract N, be at least double that of the male population of England and Wales at the corresponding ages. On referring to the Abstract given in page 106, it will be seen that, even assuming the whole of the younger officers to have been constantly resident in India or in other equally trying climates, it would not be sufficient to account for the large number of deaths which has actually taken place. The extraordinary results appearing in this paper, cannot therefore be explained by the supposed influence of climate or residence in unhealthy colonies; and it is somewhat remarkable, that in the very able statistical reports prepared from the records of the Army Medical Department, and the War-office returns, no notice should be taken of facts so seriously affecting the medical officers of the service, and so much demanding inquiry and investigation.

## MORTALITY OF MASTER MARINERS.

---

The present contribution is brought under attention with the view of increasing our knowledge of the causes which affect the mortality of Master Mariners. Apart from the scientific considerations connected with this question as a branch of Vital Statistics, it is believed that its discussion will receive additional interest from the immediate and direct application of the results to the purposes of Life Assurance Institutions.

The first portion of the following materials has been collected from the records of the "Master Mariners' Society," enrolled under the Friendly Societies' Acts, and includes the experience of the Society for the fourteen years, 1835-48. The members consist exclusively of master mariners, and previous to admission, their health and habits undergo the scrutiny usually exercised by life offices and friendly societies. The benefits granted are of a twofold nature, the payments of specified sums of money on the death of the members, and a fixed rate of compensation in the event of the wreck or partial wreck of their vessels. The registers of the Society have been very accurately kept, and the following facts have been abstracted with great care by the secretary, on a schedule prepared for the purpose, and have been at three different times compared with the original books and examined by him, so that proper means have been taken to ensure accuracy.

The facts furnished by the secretary were then re-abstracted into other schedules in the following manner.

First. All the members entering the Society in each year were distinguished and placed in separate groups according to their ages on admission, and the subsequent contingencies to be observed were, with their dates, duly noted; in the event of the death of a member, the peculiar form and manner of death, and in the event of the wreck or injury of a vessel, the particulars were always noted, and those members who did not fall under any of the causes of death, or withdrawal from the Society, were in like manner noted. The summary, therefore, of this schedule shewed for the members entering in every year of the Society's existence, and for members of different ages, the results peculiar to each, and offered interesting means of comparison, and were therefore so collected into a second schedule, the summary of which shewed, irrespective of the period of admission, the casualties of different kinds happening at each term of life. The details of these schedules occupy so much space, that it is not proposed to bring them forward here, but at once to proceed to the following Table, No. I, on which they were

finally abstracted. The following notes will be sufficient to explain the construction of this Table.

Column (*a*) Represents the age at which the admission of each member, or other contingent event connected therewith, took place.

(*b*) The number of members admitted at each age.

(*c*) The number of members remaining under observation from each preceding age, and is the residue of all those entering in each preceding age, who have not become subject to any of the contingent events represented in the adjoining columns. For example, one member enters at the age of 19, and not falling under the events specified in the adjoining columns, he survives until the succeeding age, and comes under observation as a member of the age of 20.

(*d*) Again, two members enter at the age of 20, which, with the one remaining from the age of 19, make three, coming under observation at some time or other after completing the 19th year of their life, and before completing the 20th year, none of these become subject to any of the other events specified, and the whole three are therefore carried under observation to the following age, 21, when 15 other members entered, making 18 altogether under observation at the age of 21. Of these, one, recently entered, remains alive on the 31st December, 1848, and therefore passes from under observation at the age of 21, and consequently 17 only come under observation in the next year; but at the age of 22, there are 28 members more admitted, which, added to 17, causes 45 to fall under observation in the 22nd year of life. In like manner, 77 members in all come under observation at the age of 23. Of these, one is lost during the course of that year, and one retires, while one, who has recently entered, remains alive on the 31st December, 1848, and is, therefore, not longer observed; three members in all, therefore, go from under observation at the age of 23, and 74 are carried forward to the succeeding age of 24, which, with 43 admitted at that age, brings 117 members altogether under review at the age of 24.

(*e*) Represents the numbers dying at each age or term of life from natural causes.

(*f* to *k*), inclusive, Represent the numbers dying at each age or term of life from other causes.

(*l*) Shews the total of columns *e* to *k*, inclusive.

(*m*, *n*, *o*) Shew the wrecks and loss of property.

(*p*) Represents those who have retired under the prescribed regulations.

(*q*) Represents the number of members alive on the 31st December, 1848, and who have not become subject to any of the contingent events represented in columns *e* to *k*, inclusive, and also in *p*.

(*r*) Contains the total of columns *l*, *p*, and *q*, and represents the number of members which cease to come under observation in any of the more advanced ages. For example, at the age of 25, column *d* represents 169 coming under observation; but before attaining the 26th year of age, six of these pass from observation, leaving 163 to come under the 26th year of age, as shewn in column *c*.

(*s*) Represents one half of the numbers entering the Society at each year of life at which admissions take place, and is, therefore, one half of the numbers in column *b*. In like manner, column

(*t*) Represents one half the numbers in column *p*; and column

(*u*) The total of columns *s* and *t*; the purpose of these three columns will appear in the explanation of column

(*v*) Which represents the number of lives exposed a complete year to the risk of mortality from all causes while connected with the Society, and the figures in this column are produced by subtracting  
[from the

TABLE I.

Mortality from all Causes.

| Age.     | Number Entered at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Deaths.  |          |                 |          |                   |               |          | Wrecks.  |                |          | Retired. | Alive.   | Total gone off. | Half Entered and Half Discontinued. |               |          | Number Exposed to Risk. |
|----------|-----------------------------|--------------------------------------------------------|---------------------------------------------|----------|----------|-----------------|----------|-------------------|---------------|----------|----------|----------------|----------|----------|----------|-----------------|-------------------------------------|---------------|----------|-------------------------|

from the numbers in column *d* the numbers in column *u*, opposite the same age. As already stated, column *d* contains the gross number under observation at some time or other throughout the year of life set forth in column *a*; but as column *b* contains for each age the numbers who have just entered the Society, and as members, one with another, enter at different periods throughout the year, it has been found, by observation, that, on an average, each is during the year of admission, exposed to only six months', or one half-year's mortality, and hence column *s* represents that amount of risk for all the members just admitted. In like manner, column *t* represents the amount of risk to which members retiring from the Society are exposed, on the hypothesis that, one with another, the discontinuances will take place in the middle of the year. It thus appears, that as column *u* is the total of *s* and *t*, that it shews the proper number to be deducted from the quantities in column *d*, in order to find the number exposed to the risk of a whole year's mortality.

From this Table, it will be seen that of 270 deaths, 165 only have taken place from natural causes, 62 were lost with their vessels, seven took place by violent means, such as falling of masts, and loss of life in engagements with pirates, 23 were drowned, 12 washed overboard, and one hung himself.

The following is a condensed Abstract of this Table, and represents the rate of mortality from all causes taking place among master mariners, at different periods of life.

ABSTRACT A.

| Age.       | Number exposed to<br>the Risk of Mortality<br>from all causes. | Died. | Mortality<br>per Cent. |
|------------|----------------------------------------------------------------|-------|------------------------|
| 19 to 20   | 2.5                                                            | ...   | ...                    |
| 21 ... 25  | 335.0                                                          | 6     | 1.791                  |
| 26 ... 30  | 1,405.0                                                        | 31    | 2.206                  |
| 31 ... 35  | 2,194.5                                                        | 53    | 2.415                  |
| 36 ... 40  | 2,530.0                                                        | 57    | 2.253                  |
| 41 ... 45  | 2,196.0                                                        | 52    | 2.368                  |
| 46 ... 50  | 1,390.5                                                        | 44    | 3.164                  |
| 51 ... 55  | 688.0                                                          | 21    | 3.052                  |
| 56 ... 60  | 314.0                                                          | 6     | 1.911                  |
| 61 ... 65  | 84.0                                                           | ...   | ...                    |
| 66 ... 68  | 6.0                                                            | ...   | ...                    |
| Total..... | 11,145.5                                                       | 270   | 2.423                  |

It will thus be seen that throughout the Table the rate of mortality is high; and attention is next directed to Table II, which exhibits the mortality that has taken place from natural causes only. In this Table, it will be observed that columns *a* to *e* inclusive, are exactly similar to the first five columns of Table I, but that the group of columns headed "discontinued," in Table II, consists of columns *f*, *g*, *h*, *i*, and *k*, of Table I, with the addition of *p*. The reason of this will immediately appear on reflection. In Table I, [the mortality

## Mortality from Natural Causes.

| Age.     | Number Entered at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Discontinued. |          |                |          |                   |               |          |          | Alive.   | Total gone off. | Half Entered and Half Discontinued. |               |          | Number Exposed to Risk. |

the mortality from all causes was considered, and, therefore, in the determination of the number exposed to risk, the members retiring or withdrawing from the Society, only come under the head of "discontinued," but in Table II, the mortality from natural causes only is to be measured, and, therefore, the "discontinued" group will consist not only of the retired members, but also of those withdrawing or removing from the Society by all other causes, except natural death; consequently column *s* is found by deducting from column *d* the sum of columns *p* and *q*, or column *r*. The rest of Table II will be sufficiently understood by what has been said of Table I.

The following Abstract of this Table will make the results better understood.

ABSTRACT B.

| Ages.      | Number exposed to the risk of Mortality from natural causes. | Died. | Mortality per Cent. |
|------------|--------------------------------------------------------------|-------|---------------------|
| 19 to 20   | 2.5                                                          | ...   | ...                 |
| 21 ... 25  | 333.0                                                        | 2     | .600                |
| 26 ... 30  | 1,397.5                                                      | 16    | 1.145               |
| 31 ... 35  | 2,182.5                                                      | 29    | 1.324               |
| 36 ... 40  | 2,517.5                                                      | 32    | 1.231               |
| 41 ... 45  | 2,187.0                                                      | 34    | 1.555               |
| 46 ... 50  | 1,383.5                                                      | 30    | 2.168               |
| 51 ... 55  | 685.5                                                        | 16    | 2.480               |
| 56 ... 60  | 314.0                                                        | 6     | 1.910               |
| 61 ... 65  | 84.0                                                         | ...   | ...                 |
| 66 ... 68  | 6.0                                                          | ...   | ...                 |
| Total..... | 11,093.0                                                     | 165   | 1.488               |

The preceding, which shews the rate of mortality from natural causes, will be found to be much above that for the male population of the country generally at the same ages.

The next part of this subject to be considered, is the rate of mortality from accidental causes, or rather those causes peculiar to the occupation of master mariners. Table III gives those results, and it will on consideration soon appear that in this instance the "discontinued" group must, for like reasons to those assigned in explanation of Table II, consist of the members who have died from natural causes, and those who have retired from the Society, that is, the numbers composing columns *e* and *p* of Table I. It will thus be found, that in Tables I, II, and III, the numbers exposed to the risk of mortality differ, and this arises from the fact that the peculiar contingency to be measured is different in each instance, and, hence, the difference of the quantities forming the last column of each Table. Table I measures the sum of the force of the two causes prevailing in each of the other two Tables, and, therefore, the greater number exposed to risk.

[The following

TABLE III.

## Mortality from Accidental Causes.

| Age.     | Number Entered at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Discontinued. |          |          | Deaths.  |                |          |                   |               |          | Alive.   | Total gone off. | Half Entered and Half Discontinued. |               |          | Number Exposed to Risk. |
|----------|-----------------------------|--------------------------------------------------------|---------------------------------------------|---------------|----------|----------|----------|----------------|----------|-------------------|---------------|----------|----------|-----------------|-------------------------------------|---------------|----------|-------------------------|
|          |                             |                                                        |                                             | Died.         | Retired. | Total.   | Lost.    | Violent Death. | Drowned. | Washed overboard. | Hung himself. | Total.   |          |                 | Entered.                            | Discontinued. | Total.   |                         |
| <i>a</i> | <i>b</i>                    | <i>c</i>                                               | <i>d</i>                                    | <i>e</i>      | <i>f</i> | <i>g</i> | <i>h</i> | <i>i</i>       | <i>k</i> | <i>l</i>          | <i>m</i>      | <i>n</i> | <i>o</i> | <i>p</i>        | <i>q</i>                            | <i>r</i>      | <i>s</i> | <i>t</i>                |

The following Abstract of this Table shews that in each of the three earlier quinquennial periods of life, the mortality from accidental causes is greater than in the more advanced periods of life, and should more extended inquiries confirm these results, it would be a curious circumstance to know that advanced years and increased experience enable master mariners to avoid many of the causes which occasion loss of life. There are many ways in which amongst more experienced captains this immunity from death may be accounted for, such as being in the command of a high class of vessels: but it is quite unnecessary to speculate on the cause.

## ABSTRACT C.

| Ages.      | Number exposed to the risk of Death from accidental causes. | Died. | Mortality per Cent. |
|------------|-------------------------------------------------------------|-------|---------------------|
| 19 to 20   | 2.5                                                         | ..    | ..                  |
| 21 .. 25   | 334.0                                                       | 4     | 1.197               |
| 26 .. 30   | 1,397.0                                                     | 15    | 1.074               |
| 31 .. 35   | 2,180.0                                                     | 24    | 1.101               |
| 36 .. 40   | 2,514.0                                                     | 25    | .995                |
| 41 .. 45   | 2,179.0                                                     | 18    | .826                |
| 46 .. 50   | 1,375.5                                                     | 14    | 1.018               |
| 51 .. 55   | 680.0                                                       | 5     | .737                |
| 56 .. 60   | 311.0                                                       | ..    | ..                  |
| 61 .. 65   | 84.0                                                        | ..    | .                   |
| 66 .. 68   | 6.0                                                         | ..    | ..                  |
| Total..... | 11,063.0                                                    | 105   | 0.949               |

Having thus determined the ratio of the loss of life from the various causes among master mariners, it may be interesting to shew the relation between the actual number of deaths, which has taken place from each of these causes, and that which would have happened, had the number of deaths been the same as among the male population of England and Wales, at the same ages.

## ABSTRACT D.

| Ages.      | Number of Deaths from  |                                       |                        |                                       |

Hence, it appears, that while from all causes 270 deaths happened in the Master Mariners' Society, the number of deaths which would have happened according to the mortality of the male population of England and Wales, as taken from p. 5, *ante*, is 144·683, being an increased mortality of upwards of 86 per cent., but if the mortality between the ages 21 and 60 only be taken, the increase is 90 per cent.

Again, the same Abstract shews that while the mortality from natural causes was 165, the mortality according to the ratio for England and Wales was 143·977, being a difference of about 14·5 per cent., and if ages 21 to 60 only be included, the increase is about 18 per cent. This result certainly goes against the generally received opinion, that the deaths of mariners from natural causes only, is less than in the community generally, and shews the necessity of being very careful before drawing conclusions in the absence of clearly recorded and well analysed facts. There is no doubt that many inferences may be drawn from the data here presented, applicable to some of the questions at present agitated, in regard to the health of towns, and the sanitary condition of different districts, but as these speculations do not directly bear on the subject now under consideration, they had better not be at this place entered upon.

Table IV has been prepared in order to shew whether the age, and, therefore, as a general rule, the experience of captains of vessels, has any, and what influence on the losses of property under their charge. In this Table the "discontinued group" will consist of all causes of removal from the Society, whether by death or otherwise, as vessels could not be considered under the charge of members for an entire year, unless they were, without any interruption, members of the Society for the whole term of that year, and, therefore, if death or any other cause removed them from the Society in the course of the year, a correction must be applied, as in column *p*, on that account.

[Of the

TABLE IV.  
*Risk of Wrecks.*

|          | 1,546                       |                                             | 12,041                                      | 213      | 90              | 5                     | 308      | 270           | 245      | 1,031    | 1,546    | 773.0                               | 773.0         | 1,546.0  | 10,495.0                |

Of the 308 wrecks which have taken place, it will be observed that no less than 213 have been total wrecks, 90 partial wrecks, and 5 losses by fire.

The following Abstract exhibits in a condensed form the results arrived at in this Table.

## ABSTRACT E.

| Ages.     | Number exposed to Risk of Wreck. | Total Number of Wrecks. |                 | Per Centage, Yearly, of, |                 | Total Losses. |              |
|-----------|----------------------------------|-------------------------|-----------------|--------------------------|-----------------|---------------|--------------|
|           |                                  | Total Wrecks.           | Partial Wrecks. | Total Wrecks.            | Partial Wrecks. | Number.       | Per Centage. |

| Total...  | 10,495.0                         | 213                     | 90              | 2.029                    | 0.857           | 308           | 2.935        |

It will thus be seen, that at the younger ages, the wrecks and losses of property under the charge of master mariners, is greater than at the more advanced ages, and these facts, viewed in connection with the circumstance already alluded to, that the loss of life from accidental and extraordinary events is also more frequent at younger ages, strengthens the presumption, that increased years and experience among the captains of merchant vessels, give greater security to both life and property under their charge.

Having thus shewn the principal results arrived at, attention will be next directed to the application of them to the monetary affairs of Life Offices. It is very much to be regretted, that the proprietors and managers of Life Assurance Companies should have given so very little attention to the nature of the risks which they are constantly undertaking, and have contributed little or nothing in a pecuniary point of view, to the investigation of those branches of science, by the application of which the shareholders have realized immense and most exorbitant profits, on the capital invested in such speculations. It is notorious, that notwithstanding many societies have at command a greater capital than some of the Governments of Europe, there is not a single public document extant, throwing light on the state and condition of any other class of the community than their own members, published at the expense of those societies. Of the very meagre quantity of information which does exist, all has been derived from other sources; and there is no wonder, therefore, that in these wealthy corporations there should exist the anomalous feature unknown to other matters of enterprise and industry, of the practice being much in advance of the science on which it should be founded; in fact, after the most diligent inquiries, a single instance has not been found of any one of these great and powerful Companies, which boast of their millions of invested capital,

having spent £500 in the original investigation of any single branch or department of vital statistics. It is, therefore, hoped that it will not be considered out of place to bring under attention the details of a question which, under other circumstances, would properly belong to the traders in the shares of Life Assurance Institutions.

In the preceding inquiry, an analysis has been made of the various causes of death. This is, no doubt, important as suggesting means by which, under sanitary regulations, the intensity of some of those forces may be lessened, but, for the general purposes of a Life Office, a knowledge of the gross rate of mortality is all that is required. Attention is therefore now directed to the results given in Abstract A; from which a Table of Decrements may be easily formed. In that Abstract, the rate of mortality is given for quinquennial ages only, but the intermediate terms may be found in the following manner.

Let the figures in the second column of the following Abstract represent the original quantities for quinquennial ages, derived from Abstract A, and let the columns headed  $\Delta_1$ ,  $\Delta_2$ ,  $\Delta_3$ , be the 1st, 2nd, and 3rd differences of the original quantities, also let  $(a)$ ,  $(b)$ , and  $(c)$ , which are the second and every alternate quantity in each of the three last columns, be equal to  $\cdot 2\Delta_1$ ,  $\cdot 04\Delta_2$ , and  $\cdot 008\Delta_3$ , respectively.

## ABSTRACT F.

*Differences for Interpolation of Mortality from all Causes.*

| Age. | Mortality<br>per Cent. | $\Delta_1$<br>$a = \cdot 2 \Delta_1$ | $\Delta_2$<br>$b = \cdot 04 \Delta_2$ | $\Delta_3$<br>$c = \cdot 008 \Delta_3$ |
|------|------------------------|--------------------------------------|---------------------------------------|----------------------------------------|

| 68   | 7.671                  |                                      |                                       |                                        |

Then the intervals to be interpolated being  $\frac{1}{5}$ , the intermediate terms to be inserted between the original quantities will be found as follows:—

$$\delta_1 = a - 2b + 6c$$

$$\delta_2 = b - 4c$$

$$\text{and } \delta_3 = c$$

It will be observed that there is considerable irregularity in the original quantities, as taken from Abstract A; but it was thought better not to disturb the natural results by any attempt to convert them into a graduated series. After the quinquennial period of life 50-55, the numbers are too small to warrant much reliance being placed on the results, and, therefore, subsequent to that period, an increasing series has been adopted, maintaining, as nearly as possible, the same relation at those advanced ages, to the ordinary tables of mortality for male life, as the figures in Abstract A, for younger ages, bear to the general mortality of England and Wales.

From the results thus obtained, the following Table of Decrements is derived.

TABLE V.

*Decrements and Rate of Mortality from all causes.*

| Age. | Mortality<br>per Cent.<br>= $d$ . | $\lambda l$<br>$5 + \Sigma(c) = \lambda l$<br>$\lambda\left(1 - \frac{d}{100}\right) = c$ | Number<br>Living.<br>= $l$ | Number<br>Dying. | Age. | Mortality<br>per Cent.<br>= $d$ . | $\lambda l$<br>$5 + \Sigma(c) = \lambda l$<br>$\lambda\left(1 - \frac{d}{100}\right) = c$ | Number<br>Living.<br>= $l$ | Number<br>Dying. |

From this has been constructed the following preparatory Table for the determination of the values of annuities, assurances, and other risks on the lives of Master Mariners.

Column D of Table VI has been formed for the expression  $l_m v^m$ , in which

$l_m$  represents the numbers living at the age  $m$  in the fourth column of Table V,

And  $v^m$  represents the present value of £1 due  $m$  years hence, at 3 per cent. Also, if

$D_m$  = quantity in column D, at any given age  $m$ , and

$D_{m+x}$  = do. do. at any variable higher age  $m+x$

then, in the same Table, will  $N_m = \Sigma(D_{m+x})$ , in which  $m+x$  receives every integral value from any given age, to the oldest age in the Table.

From Table V preceding, and Table C, pp. 5-6 *ante*, the following results have been obtained; shewing for different ages the equation of life for Master Mariners, and also for the male population of England and Wales.

| Ages. | Equation of Life. |                    |                      |
|-------|-------------------|--------------------|----------------------|
|       | Mariners.         | England and Wales. | Difference per Cent. |
| 21    | 29.1              | 44.0               | 51.2                 |
| 30    | 25.0              | 36.5               | 46.0                 |
| 40    | 20.9              | 28.8               | 37.8                 |
| 50    | 15.5              | 21.2               | 36.8                 |
| 60    | 10.5              | 14.3               | 36.2                 |

The foregoing is sufficient to shew the necessity of great caution in undertaking special risks on life, and the need of careful and extensive statistical research, to form a basis for calculations in this branch of life contingencies. Within the last few years, Assurance Institutions have very much increased, and the public journals sufficiently testify to the remarkable efforts made by them to extend their business among all ranks and grades of society. It is, therefore, of the first importance that those entrusted with the management of such companies, should possess accurate statistical information, to guide them in their transactions with the public. The practice of a mere arbitrary imposition of premiums for special risks unfortunately prevails to too great an extent, and is liable to very serious objections. The hazard of charging inadequate terms, may endanger the safety of the institutions, and exorbitant rates limit the practice of life assurance, while the want of clear and satisfactory data, produces distrust among the managers themselves, and deprives their efforts of that confidence and energy, which is necessary to the successful development of every enterprise. It is, therefore, hoped that the preceding facts may not be void of practical value and importance, while to the mere scientific inquirer, their novelty will recommend them to some share of attention.

It has been thought better to submit a complete analysis of one class of facts, than to bring under review a variety of data in a cursory manner: but it may be satisfactory to view, in connection with the preceding data derived from the Master Mariners' Society exclusively, another body of facts originating in other sources, namely, in the other Mariners' Friendly Societies distributed over the kingdom, and constituting a portion of the data described in pp. 17-19 *ante*, and which embraces, generally, an humbler class of sea-faring men, than the Master Mariners.

## ABSTRACT H.

| Ages.      | Number exposed to Risk. | Deaths | Mortality per Cent. | Mortality per Cent. in the Master Mariners' Society. (Abstract A.) |
|------------|-------------------------|--------|---------------------|--------------------------------------------------------------------|
| 20 to 25   | 1,562                   | 39     | 2.4968              | 1.791                                                              |
| 26 ... 30  | 5,060                   | 108    | 2.1343              | 2.206                                                              |
| 31 ... 35  | 6,842                   | 167    | 2.4408              | 2.415                                                              |
| 36 ... 40  | 7,549                   | 184    | 2.4374              | 2.253                                                              |
| 41 ... 45  | 5,783                   | 152    | 2.6283              | 2.368                                                              |
| 46 ... 50  | 3,227                   | 104    | 3.2228              | 3.164                                                              |
| 51 ... 55  | 1,716                   | 62     | 3.6130              | 3.052                                                              |
| 56 ... 60  | 651                     | 12     | 1.8433              | 1.911                                                              |
| 61 ... 65  | 119                     | 2      | 1.6882              | ...                                                                |
| Total..... | 32,509                  | 830    | 2.5531              | 2.423                                                              |

The rate of mortality, it will be seen, differs but slightly in the two classes of results, and calls for no particular commentary. Connected with this last body of facts, there has also been made a return of the amount of sickness or invaliding: but the discussion of that part of the inquiry must be reserved for a subsequent part of these contributions, in which the question of sickness generally will be considered.

## MORTALITY OF THE PROVIDENT CLASSES IN THIS COUNTRY AND ON THE CONTINENT.

---

In the present Contribution it is intended to exhibit the rate of Mortality which prevails among the Wealthy, the Middle, and the Provident Classes of this Country and of the Continent.

It has been shewn in pp. 93-9 *ante*, that until the beginning of this year England and Wales were the only portions of the United Kingdom in which public mortuary registers were kept, and, consequently, in which the rate of mortality of the whole population could be accurately measured. In the other divisions of the kingdom, the rate of mortality is known only inferentially, and not by direct observation, and nowhere do the published portion of the public records, as fully explained in pp. 10-16 *ante*, afford the means by which to determine the duration of life in particular classes of the community. There are, however, other sources from which much information may be derived.

In the year 1843, a report was made, by a committee of actuaries, on the mortality among the persons assured by seventeen of the principal assurance companies of this country, (see Table H, col. 5, pp. 40 1,) and these persons may be fairly considered to belong to the middle and upper classes of society; and at various periods since the year 1824, inquiries have been made into the rate of mortality among the members of friendly societies, including the more industrious and prudential of the working and the labouring portion of the people. One important result derived from these investigations is, that while the mortuary registers shew a certain rate of mortality for the whole population of England and Wales, the evidence furnished by the facts constituting the other body of information clearly proves the mortality of the middle and upper classes to be above, and that of the industrious working classes to be below, the ratio for the country generally. This conclusion forms an important consideration in all sanitary inquiries; and, by an obvious inference, determines in what class or section of the people the excessive rate of mortality prevails. For other reasons, however, it is a subject of the first importance to understand clearly the rate of mortality among the middle and upper classes.

The *Journal of the Statistical Society* contains a valuable body of evidence on this question, which goes to prove that among the peerage, the country gentry, and the professional classes, the rate of mortality is higher than that of the country generally: and, as already pointed out in pp. 42-3, the report by the committee of actuaries shews, that among the lives assured by the public companies of this country, the mortality is also not less than that of the general population.

In support of the results derived from this latter body of facts, there is abundant collateral proof; but it has been thought desirable to test them, if possible, by facts originating in quite an independent source. With this view, an analysis has been made of the experience of some of the life assurance offices in Germany, one of which, the Gotha Society, the largest in the world, had, in the 21 years ending January 1850, assured 22,063 lives. There were, in the beginning of the year 1850, subsisting assurances on no less than 15,471 of these lives; and, on the 1st of January of the present year the number of lives assured was 18,858.

From the following Tables, it will be seen that a very elaborate investigation has been made of the facts presented, and that some of the combinations formed are of a novel character in vital statistics; but a very few observations will suffice to bring the results under criticism, as the various Tables and Abstracts sufficiently explain themselves. It should be stated that the information is collected from the very admirable annual reports of the Gotha Life Office, and that wherever tabulated results were furnished in these documents, their accuracy has been tested by a reconstruction of the figures from the original abstracts.

The following Table exhibits the rate of mortality in this Society for each of the eight years 1842-49, and the difference for each quinquennial term of life between the actual rate of mortality and that expected according to the data on which the rates or scale of premiums in use by the Society are based, named, a rate of mortality assimilating closely to the "Equitable Experience."

TABLE I.

| Age.     | 1842.    |         |           | 1843.    |         |           | 1844.    |         |           | 1845.    |         |           |

| 66 .. 70 | 459      | 30      | 20.47     | 473      | 24      | 21.36     | 523      | 32      | 23.79     | 553      | 46      | 24.95     |
| 71 .. 85 | 205      | 19      | 16.76     | 252      | 24      | 20.80     | 294      | 33      | 24.45     | 341      | 34      | 28.39     |
| Total..  | 14,564   | 229     | 257.03    | 15,361   | 293     | 275.53    | 15,652   | 339     | 290.27    | 16,047   | 337     | 302.28    |

An inspection of the preceding Table will shew, that in four out of the eight years, there has been experienced a greater number of deaths, than expected according to the Tables of the Society, namely, in the years 1842, 1847, 1848, and 1849; and, according to the following Abstract, it will be seen that the excess of deaths for the whole of the eight years has been 43·47, being about 2·180 per cent. on the expected mortality.

## ABSTRACT A.

*Mortality during the Years 1842—1849.*

| Ages.     | Number of Persons Assured. | Actual Deaths. | Sum of Actual Deaths. | Expected Deaths. | Sum of Expected Deaths. |
|-----------|----------------------------|----------------|-----------------------|------------------|-------------------------|
| 15 to 25  | 909                        | 2              | ...                   | 5·7              | ...                     |
| 26 ... 30 | 4,353                      | 29             | 31                    | 35·9             | 41·6                    |
| 31 ... 35 | 10,664                     | 86             | 117                   | 104·4            | 146·0                   |
| 36 ... 40 | 17,605                     | 180            | 297                   | 157·9            | 343·9                   |
| 41 ... 45 | 21,721                     | 218            | 515                   | 263·2            | 607·1                   |
| 46 ... 50 | 19,657                     | 281            | 796                   | 297·3            | 904·4                   |
| 51 ... 55 | 15,487                     | 269            | 1,065                 | 306·0            | 1210·4                  |
| 56 ... 60 | 11,003                     | 313            | 1,378                 | 278·9            | 1489·3                  |
| 61 ... 65 | 6,789                      | 284            | 1,662                 | 222·6            | 1711·9                  |
| 66 ... 70 | 3,433                      | 226            | 1,888                 | 153·5            | 1865·4                  |
| 71 ... 85 | 1,597                      | 149            | 2,037                 | 128·2            | 1993·6                  |
|           | 113,218                    | 2,037          |                       | 1993·6           |                         |

It is worthy of remark, at this point of the inquiry, that, under the age of 55, the actual rate of mortality is uniformly less than the expected rate, averaging about 12 per cent. less than the rate calculated upon; but, on the other hand, the actual mortality above the age of 55 exceeds the expected mortality about 24 per cent. A comparison of the columns headed "persons assured," for each of the nine years represented in Table I, with the figures in the fourth column of Table XV, following, will shew that the number of persons given in Table I, for each year, is the gross number assured, and not the number exposed to the risk of a whole year's mortality; it would, therefore, lead to a false estimate of the mortality, were it to be measured with reference to the numbers in the columns headed "persons assured;" but this has evidently not been done in the determination of the numbers in the columns headed "expected deaths;" they are derived from the correct number exposed to a whole year's risk of mortality.

It will be observed that the excess of 43 deaths over the expected number in Table I and Abstract A preceding, is due chiefly to the years 1848-9; in the former year, the difference being about 49, and in the latter 35 deaths, the united difference being nearly double that of the gross difference for the eight years under review. It is, therefore, obvious that this result depends on some temporary cause, namely, epidemics prevalent in those years, as will be hereafter seen.

If reference be now made to Table II, which gives the history of the 1285 lives assured in the first year of the Society's existence, it will be found that, at the end of the

year 1838, there had been 196 deaths; the policies on the lives of 124 had lapsed; and 965 persons still remained assured; irrespective of all those assuring subsequent to the year 1829. It will be further seen that the actual number of deaths is almost identical with the number expected, according to the data on which the Society's calculations are based: corresponding very closely with the rate of mortality observed among assured lives generally in this country. It will be further seen that, except at the quinquennial term of life, 56-60, at which the numbers assured are very small, and therefore subject to fluctuation, there is no very important difference between the actual and expected rate of mortality.

TABLE II.

| Ages.     | Number of<br>Persons<br>Assured in<br>1829. | Deaths during 1829—1838. |                     |         |                   | Number of<br>Lives upon<br>which Policies<br>have Lapsed. | Number of<br>Policies sub-<br>sisting at the<br>end of 1838. |

The following Table (III) exhibits the rate of mortality among the members of the Society for the twenty-one years 1829-49; and it will be seen, that while the expected mortality was 3193.83, the actual deaths have been 3144, falling short of the expected mortality by about 50 deaths, or 1.560 cent. lower than the expected mortality. It will also be observed that in this, as in Abstract A, the actual exceeds the expected mortality by 19.3 per cent. above the age of 55, but is less under that age by 12.7 per cent. A comparison of the facts presented in this Table, with those in Table II and Abstract A, shews, in a remarkable degree, the amount of deterioration which takes place in the health of the assured after the expiration of a few years from the date of admission. In Table III, the actual number of deaths falls short of the number expected by the Tables of the Society about 1.560 per cent., but in Abstract A, the actual mortality exceeds the expected by 2.180 per cent. The former body of facts embraces all the members of the Society, not only those originally admitted, but also those recently enrolled; and while it includes the mortality of the older class of members long subsequent to their admission, it also contains the mortality in the early years of admission in the same class, and, at the same time, the mortality of those persons but recently admitted. On the other hand, the latter body of facts (Abstract A), although it contains the mortality of members recently admitted, or those entering the Society subsequent to the year 1841, yet it does not contain the mortality for

the older class of members for any of the years preceding 1842; and although, as already remarked, this excess of mortality may be partly due to the epidemics of 1848-9, still it is obvious that the increased mortality is also to some extent owing to the exclusion of the experience of the first fourteen years of the older class of members. That this must be the case, is further evident, from a consideration of the results in Table II, which must be regarded as intermediate between the two other groups of facts just alluded to, as it is free from the admixture of the recently-admitted members with the older, all having been admitted in the year 1829; and it will be observed, that the actual number of deaths is almost identical with that expected by the Tables of the Society; while also, in respect to Table II, it will be observed that there is much greater uniformity in the actual and expected deaths at the different terms of life than in either Abstract A or Table III, and this result is consistent with the exclusion of the new admissions, chiefly taking place at the younger terms of life, in the two other classes of facts.

TABLE III.

*Mortality during the Years 1829—1849.*

| Ages.     | Number of Persons Assured. | Actual Deaths. | Sum of Actual Deaths. | Expected Deaths. | Sum of Expected Deaths. |
|-----------|----------------------------|----------------|-----------------------|------------------|-------------------------|
| 15 to 25  | 1,931                      | 8              | ...                   | 12.0             | ...                     |
| 26 ... 30 | 9,199                      | 71             | 79                    | 73.8             | 85.8                    |
| 31 ... 35 | 22,490                     | 189            | 268                   | 214.6            | 300.4                   |
| 36 ... 40 | 33,928                     | 304            | 572                   | 373.1            | 673.5                   |
| 41 ... 45 | 37,228                     | 356            | 928                   | 442.0            | 1115.5                  |
| 46 ... 50 | 32,362                     | 440            | 1,368                 | 481.5            | 1597.0                  |
| 51 ... 55 | 25,016                     | 450            | 1,818                 | 485.9            | 2082.9                  |
| 56 ... 60 | 17,618                     | 481            | 2,299                 | 440.3            | 2523.2                  |
| 61 ... 65 | 10,370                     | 412            | 2,711                 | 334.8            | 2858.0                  |
| 66 ... 70 | 4,477                      | 271            | 2,982                 | 198.6            | 3056.6                  |
| 71 ... 85 | 1,734                      | 162            | 3,144                 | 137.3            | 3193.9                  |
|           | 196,353                    | 3,144          |                       | 3193.9           |                         |

In order to determine the relation between the actual rate of mortality prevailing among the members of the Gotha Life Society and that of other classes of lives, it is necessary, in the first place, to ascertain the number of persons exposed to the risk of a whole year's mortality at the different terms of life, and this may be easily done by the following formula, in which

$a$  = the total number of persons entering the Society during the whole 21 years, as given in column 3, Table XV.

$b$  = the total number of persons on whose lives policies have lapsed from other causes than death, during the same period of years, as given in column 5, Table XV.

$c$  = the gross number of persons assured at one time or another during the same 21 years, as set forth in column 2, Table III, for the same terms of life at which members

enter or retire from the Society; and, therefore,

$\frac{a+b}{c} \cdot \frac{100}{2}$  = the quantity to be deducted from column 2, Table III, for the same period of life, in order to determine the gross number exposed to the risk of a whole year's mortality. But this quantity cannot be applied as an average ratio to each term of life, as the admissions and demissions are not uniform over each term or period of life in the Table. Let, therefore, the figures in columns 2 and 7 of Table II represent the correct ratio of persons entering the Society, and also withdrawing from all causes, death excepted; also let

$d$  = the total of the numbers in columns 2 and 7 for any term of life in Table II;

$e$  = the sum of the numbers in the two columns 2 and 7 for any given term of life; and

$n$  = the number of the terms of life at which members enter and withdraw; then

$$\lambda x = \lambda e + \lambda \left( \frac{a+b}{c} \cdot \frac{100}{2} \cdot n \right) - \lambda d. \quad \text{And if}$$

$f$  = the quantity at any particular term of life in Table III; then will

$f \cdot (100 - x)$  = the number forming the second column of the following Table.

TABLE IV.

| Age.      | Number exposed to the risk of Mortality for a whole Year. | Number of Deaths that would have happened according to the Mortality of England and Wales. Males. | Sum of the Deaths. | Actual Deaths in the Society. | Sum of Actual Deaths. |
|-----------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------|--------------------|-------------------------------|-----------------------|
| 15 to 25  | 1,912                                                     | 15.6                                                                                              | ...                | 8                             | ...                   |

|           | 179,884                                                   | 3196.7                                                                                            |                    | 3,144                         |                       |

Column 3 of the preceding Table shews, that if the rate of mortality in the Society had been the same as among the male population of England and Wales, (Table C, pp. 5-6 *ante*) the total number of deaths would have been 3196.59, while, according to column 5 of Table III, the expected mortality by the Tables of the Society was 3194, and, as in column 5 of the present Table, the actual mortality had been 3144. It is therefore evident that the average rate of mortality for the whole population of this country does not, for the whole term of life under observation in Table IV, differ in any important degree from the rate assumed for the basis of the Society's calculations; and it is further evident from a comparison of the last column of Table III, with columns 4 and 6 of Table IV, that the rate of mortality among the general population of England and Wales

approximates nearer to the actual rate of mortality experienced by the Society for the respective terms of life, than the rate assumed in the construction of the Society's Tables; shewing that Table C, just alluded to, is better graduated for practical purposes, than that in actual use by the Society.

In Table V will be found the rate of mortality according to various series of observations. The results in column 2 are deduced from columns 2 and 5 of Table IV, and, therefore, represent the rate of mortality experienced in the Gotha Life Office. And it will be seen, that throughout the whole of life, the mortality is almost always less than among the peerage or the males of the government annuitants, and not differing widely from the results for the whole male population of England and Wales, and those for the lives of the assurance societies in England, but the mortality is much above that experienced by the members generally of friendly societies in England and Wales. A consideration of the peculiar features and constitution of those humble provident institutions, will fully explain the reasons of this increased longevity among the industrious and provident portion of the working classes of this country. This part of the question has already been treated at length in pp. 17-101 *ante*. Column 4 in the following Table represents the rate of mortality as observed among the male members generally of friendly societies throughout England and Wales; but if reference be made to Appendix A of the

TABLE V.

| Age       | Rate of Mortality per Cent. according to the |                                             |                                                                                |          |                               |                                 |

Report of the Select Committee of the House of Lords appointed to consider certain matters connected with Provident Associations, session 1847-8, paper No. 126, some interesting examples will be found of remarkable differences in the rates of mortality and sickness in those societies. In a very able paper by Mr. Farr, in the second edition of "M'Culloch's Statistics of the British Empire," it is stated that there is reason to believe that further inquiries will shew that not only sickness, but mortality, will increase in

friendly societies generally; and the results of a recent investigation among the members of Odd Fellow Societies appear to support this opinion, so far as respects mortality. The facts brought forward in the "Contributions on the Rate of Mortality in the Medical Profession," pp. 112-133 *ante*, will also be found to be strikingly corroborative of the general principle which seems to regulate the mortality of other classes, namely, that the humble but industrious working classes, whose prudential habits lead them to become members of these societies, are subject to a less rate of mortality than any other, and that the higher the class of society over which the observations extend, until the peerage, or highest class of all, is observed, in which there is less of the regular and healthful daily exercise essential to the condition of the industrious workman, the greater the rate of mortality; and for intermediate classes, a varying degree of mortality is observable, following pretty closely the scale of their position in social rank.

From the facts brought forward, it appears that the duration of life in the German States of Europe, among the higher provident classes, who embrace the principles of life assurance, is fully equal to that among the like classes in this country, and the value of life amongst those classes approximates closely to the rate of mortality for the general population of England and Wales; but the humbler provident classes who enrol themselves members of friendly societies in this country, enjoy a prolonged duration of life above all others.

That an idea may be formed of how far the results in Tables I, II, III, IV, and the second column of Table V, may be indicative of the state of health of the populations of the different German States, it may be important to shew the number of persons assured for the middle of the period of the 21 years 1829-49, namely, at the end of the year 1838 in each of those districts.

| District.                                                   | Persons. | In every<br>100,000<br>Inhabitants. | District.                                         | Persons. | In every<br>100,000<br>Inhabitants. |

The greatest number of the assurers, nearly 49 per cent. of the whole, are in Prussia;

but the States having the greatest proportion of its population assured, are the Ducal and Grand Ducal Saxon territories; and those having the least proportion assured, are the Danish and Swiss German territories.

With the view to determine whether any and what law prevailed in relation to the period which has elapsed from the date of assuring to the date of death among those persons dying in the years 1839-49, distinguishing the age at the time of being assured, a detailed Abstract has been made of each policy, classifying together those of the same age at the date of assuring, and at the same time setting forth the period elapsing until the day of death, and thence arriving at the average period which elapsed from the date of taking out their policies till the day of death, for those entering the Society at different ages. The following Table shews the results arrived at:—

TABLE VII.

*Period elapsed from the date of Assuring, till Death, of those Dying among the Assured, during the Years 1839-49.*

No very distinct or obvious difference is here observable in the various classes of results; and attention is therefore directed to the following Abstract:—

## MORTALITY OF THE PROVIDENT CLASSES

## ABSTRACT C.

*Period elapsed from the date of Assuring, till Death, of those Dying among the Assured, during the Years 1839-49.*

| Age.     | Number of Deaths. | Duration of Life. |         | Duration of Life to each Person. |         | Duration of Life. |         | Duration of Life to each Person. |         |

| Total .. | 2,471             | 22,778            | 9       | 9                                | 3       |                   |         |                                  |         |

In which it will be seen, contrary to what would generally be expected, that the period which elapsed from the date of the policies to the date of death is less at the younger than the older ages; so that, if such a law were found generally to prevail, it would follow that a Life Office should find the deaths taking place among the younger lives more immediate than among the older class of lives. Whether this unexpected and apparently anomalous result may arise from the fact that, at the earlier ages, the deaths take place from acute and rapidly-fatal diseases, while at the advanced periods of life, they happen from chronic and lingering causes, is not clearly borne out by the analysis as far as it has yet proceeded; but that such is very probably the case, will appear from a consideration of the preceding

| Age.     | Per Centage of Members Sick during each Year. | Ratio of Sick Members to every 100 not Sick in every Year. | Mortality per Cent. among those Actually Sick. | Sickness per Annum among those Actually Sick. | Total amount of Sickness to each Death. |

figures, derived some time ago from the experience of friendly societies in Scotland, from which very accurate and interesting returns were received and carefully analysed.

It is therefore evident that, from the younger to the more advanced ages, there is, among all classes, a uniformly increasing rate of sickness to each death. At the term of life 31-5, there are 116 weeks' sickness to each death, and the rate goes on increasing to the period 76-80, in which the amount of sickness is 319 weeks to each death.

However, the preceding simply shews the average amount of sickness among all the members of a society to each death taking place among the same members at different ages; and the results are not fairly applicable as illustrative of the principle or law manifested in Abstract C, in which it would appear that the period which has elapsed between the date of effecting policies and the date of death of the persons assured thereunder, is less at the younger than at the older ages. For, to determine whether this law has any connection with the more acute forms of disease peculiar to younger ages, only the resulting sickness ending in death, or among those finally dying, at the given terms of life under consideration, should be measured; but it may be interesting, and also important, to shew the average duration of sickness not ending in death, as well as of that proving fatal.

In the following Abstract will be found the results of 5640 attacks of sickness, resulting in recovery; from which it appears that the average duration of each attack is 8.636 weeks: but it is necessary to observe how very much the duration of sickness depends on the age of the persons affected; under the age of 35, the average duration of each attack is about 4.372 weeks; from that to the age of 50, each attack lasts about 5.131 weeks; in the subsequent period of ten years, the duration of each attack is 11.717 weeks; and beyond that age (60), it will be seen that sickness becomes very protracted.

#### ABSTRACT D.

*Duration, in weeks, of Sickness ending in Recovery.*

| Age.     | Attacks. | Sickness. | Average Duration of each Attack. |

It should be clearly kept in view, that the Abstract just given represents such sickness only as ended in the recovery of the members; but in the following Abstract are given the results of 1012 attacks of sickness among 437 persons, whose deaths took place at the terms of life represented in the Table. The figures given in columns 8, 9, and 10, of this Abstract, differ in a remarkable manner from the results at corresponding ages in Abstract D.

## ABSTRACT E.

*Duration, in weeks, of Sickness ending in Death.*

| Age.     | a.<br>Total<br>Amount of<br>Sickness. | b.<br>Amount of<br>Sickness<br>immediately<br>before Death. | a-b.<br>Amount<br>not ending in<br>Death<br>of those<br>afterwards<br>Dying. | c.<br>Attacks. | d.<br>Persons. | c-d.<br>Attacks<br>not ending<br>in Death<br>of those<br>afterwards<br>Dying. | Average<br>duration of<br>each Attack in<br>Total Sickness of<br>those afterwards<br>Dying | Average<br>duration of<br>Attack<br>immediately<br>before Death. | $\frac{a-b}{c-d}$<br>Average<br>duration of<br>Attacks not<br>ending in Death<br>of those after-<br>wards Dying. |

It will be seen that column 8 represents the average duration of each attack of sickness, including that ending in death, as well as preceding attacks of sickness. In Abstract D, under the age of 35, it was 4.372 weeks; but in column 8, the average duration is 10.830 weeks; and in the more advanced periods of life, a similar increase in the duration of sickness is observable; so that it would seem to follow that the duration of sickness is greater among those dying at periods not very remote from the attacks, than among those surviving; and, consequently, if the duration simply of sickness be closely observed, it offers an element of considerable importance in measuring the expectation or future lifetime of individuals. In Abstract D, the average duration of each attack of sickness for all ages is 8.636 weeks; but in Abstract E, the average duration is 23.932 weeks. The former class of facts relates to persons who all survived the period of twelve years over which the observations extended; but the latter class belongs to persons all of whom died within the same period of twelve years. The force of this conclusion will be more strongly felt, if attention be directed to the figures in column 9, which represent the average duration of the attack of sickness ending in death, at which it will be seen that at every term of life the fatal attack of sickness is of much greater duration than

those represented in column 8, or in Abstract D. The following condensed Abstract will assist in giving a general view of those results.

| Age.           | Average Duration of each Attack of Sickness. |                                                                                |                                                     |                                                                                                          |

| Total.....     | 8.636                                        | 7.788                                                                          | 45.173                                              | 23.932                                                                                                   |

It is hence obvious, that having regard to the ages of persons, the duration of any attack of sickness is a most important consideration in calculating the chances of recovery. If another element, the frequency of a series of attacks of sickness, were introduced (but the details it would here be out of place to discuss), the value or the duration of life of invalids may be calculated with even more precision than the expectation of life of the general community; and if the analysis were carried one step further, and the same classification adopted as in the preceding Abstracts, only keeping the sickness peculiar to each disease by itself, a series of results would be arrived at, furnishing elements of the greatest value in the estimation of the value of life among persons who have suffered or are suffering from disease. Notwithstanding the immense pecuniary interests at stake by life offices, no inquiry or investigation of this kind has ever been undertaken by them, and the preceding and other similar collections of facts, are, it is believed, the only sources of information so analysed which anywhere exist. From the specimens now furnished from the records of friendly societies, the very remarkable aids which they must afford in estimating the value of peculiar classes of lives, by confining fluctuations within known limits, must be evident. The trouble and expense of collecting such data is very great, but still the information itself is of tenfold value to the life institutions of the country.

In the following Abstract will be found the combined results of Abstracts D and E, preceding; and in this, as in all the others, will be found evidence of the same general principle or law of nature which has led to this investigation of the duration of sickness peculiar to different terms of life, namely, that the duration of sickness either in the attacks immediately preceding death, or otherwise, is less protracted at the younger and middle periods of life, than at the more advanced; and hence the solution of the otherwise anomalous facts arrived at in Abstract C, that of the deaths which have taken place among the lives assured at the earlier ages, the time elapsed from the date of the policies to that of death is less than among those assured at the more advanced ages.

## ABSTRACT F.

*Average Duration, in weeks, of Total Sickness.*

| Age.     | Total Number of Attacks, including those ending in Recovery and those ending in Death. | Total Amount of Sickness, including that ending in Recovery and that ending in Death. | Average Duration of each Attack of Sickness, including that ending in Recovery, and that ending in Death. | Number of Attacks, including those ending in Recovery, and those not ending in Death of those afterwards Dying. | Amount of Sickness, including that ending in Recovery, and that not ending in Death of those afterwards Dying. | Average Duration of each Attack of Sickness, including that ending in Recovery, and that not ending in Death of those afterwards Dying. |

Attention is next directed to the following Table, which is somewhat analogous in its character to Abstract C, only that the element of age, with the view to its more simple application to practical purposes, is excluded. From the register of deaths for the years 1840-9, an abstract has been made of those which have taken place in the first, second, third, and every subsequent year from the date of the policies; and the results constitute the following Table:—

TABLE VIII.

| Year.                     | Deaths among the Assured after the lapse of the following Number of Years from the Date of Assurance. |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |        |

| Order of }<br>Mortality } | 6                                                                                                     | 9   | 8   | 10  | 10  | 12  | 13  | 15  | 18  | 11  | 14  | 16  | 17  | 11  | 9   | 7   | 5   | 4   | 2   | 3   | 1   |        |

On referring to Abstract C, it will be found that the average period which had elapsed from the date of the policies to the day of death, was nine years and three months; and in the preceding Table it will be also seen, that the greatest number of deaths took place in the ninth year after the date of the policies, the oldest policy being then about twenty-one years. During the five years 1840-4, it is curious to observe, that the greatest number of deaths was also among policies of nine years' standing, although the oldest policy was then of sixteen years' duration only; and it is still further to be observed, that during the five years 1840-4, about one-half of all the deaths took place in the first eight years of the policies; but for the ten years 1840-9, one-half of all the deaths happened in the first nine years, the oldest policies being, in the latter case, of five years' greater duration. At the same time it will be seen that the number of deaths per annum has gone on increasing from 143, in 1840, to 337 in 1849—in the former year, the number of persons assured being 10,234, and in the latter, 15,036; so that, although the number of persons assured increased about 48 per cent., the deaths increased to the extent of 136 per cent. The numerals at the top of the Table shew the duration of the policies, and those in the bottom line of the Table shew the order in which the deaths took place, from the minimum, in the twenty-first year, to the maximum, in the ninth year. It is obvious that the solution of the results here presented will be derived from the law of mortality exhibited in Table IV, the number of persons assured in each year, and the ages of those persons; and that any fluctuation whatever taking place in any one of these elements, must disturb the results set forth in Table VIII. This is observable in Abstract C, the age of the persons assured shewing an important influence on the duration of the policies.

There are also other important practical considerations, as well as those of a more

strictly philosophical and scientific nature, connected with the period of the year at which the deaths took place, and it may therefore be interesting to shew how far the seasons affect the number of deaths in the aggregate, as well as at the different ages or terms of life. In the following Table will be found an analysis of all the deaths which took place in the eleven years 1839-49, distinguishing the months of the year in which they happened, and also the ages at death:—

TABLE IX.

*Ages at which the Deaths among the Assured took place in different Months, during the Years 1839—49.*

| 55 ... 59 | 31      | 32   | 30     | 36     | 30   | 29    | 22    | 29   | 29    | 21   | 41   | 33   | 363    |
| 60 ... 64 | 25      | 23   | 41     | 28     | 34   | 19    | 35    | 23   | 31    | 34   | 36   | 26   | 355    |
| 65 ... 69 | 21      | 28   | 29     | 28     | 21   | 26    | 18    | 14   | 22    | 19   | 26   | 19   | 271    |
| 70 ... 74 | 11      | 12   | 12     | 7      | 16   | 10    | 13    | 9    | 9     | 14   | 10   | 16   | 139    |
| 75 ... 79 | 5       | 3    | 3      | 5      | 4    | 2     | 2     | 2    | 3     | 3    | 6    | 4    | 42     |
| 80 ... 84 | 1       | 2    | 1      | ...    | ...  | ...   | ...   | ...  | ...   | ...  | ...  | 1    | 5      |
| Total...  | 193     | 195  | 251    | 214    | 221  | 178   | 194   | 173  | 207   | 196  | 226  | 223  | 2,471  |

It thus appears that the greatest number of deaths took place in the month of March, and the least in the month of August; the three months of least mortality being August, June, and January; the three months next in order being July, February, and October; then September, April, and May; and the three months of highest mortality are December, November, and March. If, however, the year were divided into quarters of consecutive months, it will be found that they stand in the following order:—

| Quarter in which the Mortality is of |                   |                  |                    |
|--------------------------------------|-------------------|------------------|--------------------|
| Lowest Intensity.                    | Second Intensity. | Third Intensity. | Highest Intensity. |
| June                                 | December          | September        | March              |
| July                                 | January           | October          | April              |
| August                               | February          | November         | May                |

The months of March, April, and May, it will be seen, constitute the quarter of highest mortality; and out of the following five classes of facts, it will be found that, in three instances, they constitute the quarter of highest mortality, and the month of March enters into the highest quarter of four out of the five groups of facts.

| April . . . . .       | 2,424  | January . . . . .              | 1·16        | January . . . . .       | 7,090       |

But in respect to the quarter of least mortality, the results are more variable. July enters into four of the five groups, June into two, and August into only one. These remarks have reference to the aggregate mortality only, but if reference be now made to Table IX, it will be seen that the seasons have a very material influence on the mortality of different ages. The following Abstract exhibits the results for different terms of life.

ABSTRACT G.

| Ages.                  | MONTHS. |      |        |        |      |       |       |         |       |          |      |      | Total. |
|------------------------|---------|------|--------|--------|------|-------|-------|---------|-------|----------|------|------|--------|
|                        | Jan.    | Feb. | March. | April. | May. | June. | July. | August. | Sept. | October. | Nov. | Dec. |        |
| Under 40 . . . . .     | 26      | 33   | 37     | 23     | 28   | 24    | 32    | 31      | 34    | 36       | 28   | 39   | 371    |
| 40—59 . . . . .        | 104     | 94   | 128    | 123    | 118  | 97    | 94    | 94      | 108   | 90       | 120  | 118  | 1,288  |
| 60 & upwards . . . . . | 63      | 68   | 86     | 68     | 75   | 57    | 68    | 48      | 65    | 70       | 78   | 66   | 812    |
| Total.....             | 193     | 195  | 251    | 214    | 221  | 178   | 194   | 173     | 207   | 196      | 226  | 223  | 2,471  |

It thus appears that under the age of 40, the least mortality has been in the month of April, and the greatest in the month of December; but in the term of life 40-59, the least mortality has been in the month of October, and the highest in the month of March. Again, in respect to the most advanced term of life, those aged 60 and upwards, the least mortality has, as in the case for the aggregate of all ages, been in the month of August, and the highest likewise in the month of March. The following, then, will represent the quarters of highest and lowest mortality:—

|                                   | Ages at which the Deaths happened. |                               |                               |                               |
|-----------------------------------|------------------------------------|-------------------------------|-------------------------------|-------------------------------|
|                                   | Under Age 40.                      | Ages 40—59.                   | Aged 60 and upwards.          | Results for all Ages.         |
| Quarter of Least Mortality ... }  | April, May, June.                  | June, July, August.           | June, July, August.           | June, July, August.           |
| Quarter Second in Intensity }     | July, August, September.           | December, January, February.  | December, January, February.  | December, January, February.  |
| Quarter Third in Intensity .... } | January, February, March.          | September, October, November. | September, October, November. | September, October, November. |
| Quarter of Highest Mortality }    | October, November, December.       | March, April, May.            | March, April, May.            | March, April, May.            |

Hence, by dividing the year into quarters formed of consecutive months, representing the highest and lowest mortality, it will be seen that the combinations agree for all the terms of life except those for ages under 40: and this is in conformity with the results already observed under Abstracts C, D, E, and F; the more acute form of diseases peculiar to those ages being differently affected by changes of temperature and seasons; but if, instead of the combinations into quarters, the mortality be arranged in the order of the months, a much greater disparity in the results will be observable:—

|    | Order of the Months of Lowest and Highest Mortality, for those Dying aged |           |                 |           |
|----|---------------------------------------------------------------------------|-----------|-----------------|-----------|
|    | Under 40.                                                                 | 40—59.    | 60 and upwards. | All Ages. |
| 1  | April                                                                     | October   | August          | August    |
| 2  | June                                                                      | February  | June            | June      |
| 3  | January                                                                   | July      | January         | January   |
| 4  | May                                                                       | August    | September       | July      |
| 5  | November                                                                  | June      | December        | February  |
| 6  | August                                                                    | January   | February        | October   |
| 7  | July                                                                      | September | April           | September |
| 8  | February                                                                  | May       | July            | April     |
| 9  | September                                                                 | December  | October         | May       |
| 10 | October                                                                   | November  | May             | December  |
| 11 | March                                                                     | April     | November        | November  |
| 12 | December                                                                  | March     | March           | March     |

The influence of the seasons on the mortality at different ages is hence obvious, and there can be little doubt that a more extended series of observations would lead to a well defined law in this respect. The importance of the question to life institutions and to

science, it is hoped, will induce those interested in such objects to investigate the matter further.

The next part of this inquiry to be brought under consideration is that which relates to the disease, or cause of death. The Report of the Gotha Society for the year 1838 contains an abstract of the causes of death for the ten years 1829-38, arranging the diseases according to a general and popular form of classification; and the Report for the year 1848 contains a similar abstract for the twenty years 1829-48. The following shews the results arrived at:—

## ABSTRACT H.

| DISEASE.                                | Number of Deaths during the Years |           |           |           |           |        |               |           |           |           |           |           |        |
|-----------------------------------------|-----------------------------------|-----------|-----------|-----------|-----------|--------|---------------|-----------|-----------|-----------|-----------|-----------|--------|
|                                         | 1829 to 1838.                     |           |           |           |           |        | 1829 to 1848. |           |           |           |           |           |        |

The preceding Table represents the ratio of deaths which have taken place from six principal classes of disease during each decennial period, and during the whole twenty years, without distinction of ages.

From a subsequent Table, it will be found that the average age of the assured varied, in the twenty years to which the preceding figures relate, from 43 years to 47 years, and hence might be expected an increased number of deaths from apoplexy, which is generally believed to press with greater intensity as age increases; such, however, it will be seen, is not the case, so far as the preceding facts are concerned, for, in the first decennial period, the deaths from apoplexy formed about 17 per cent. of the whole, while in the second ten, the deaths from that cause were a little above 13 per cent. only. There can be no doubt that this difference is, to a great extent, if not entirely, due to the small number of deaths included in the first period; and it will be, therefore, more advantageous to examine the results in connection with the number of lives exposed to the risk of mortality at the various terms of life. The following exhibits, therefore, the ratio of deaths per cent. to the population exposed to the risk of mortality from different causes, according to the preceding classification of disease:—

TABLE XI.

| DISEASE.                      | Ratio of Deaths from Different Causes during 1829 to 1848, at the following Ages. |                     |                |                     |                |                     |                |                     |                |                     |                |                     |                |                     |

In the class of disease denominated fever, in the preceding Table, it will be seen that the mortality uniformly increases from the younger to the older ages. With respect to the group of diseases “local inflammation,” it will be seen, that although there is an increase

in the rate of mortality from the younger to the older ages, still the difference is very slight under the age of 50, and the intensity greatest of all at the term of life 61-70. Again, with respect to "chronic pulmonary diseases," the bulk of the deaths took place between the ages of 31-70, and the rate of mortality increases from .245 per cent. in the term of life 31-40, to .351 per cent. at ages 61-70. In the class "chronic abdominal diseases," the mortality increases in a very rapid manner from the younger to the older ages, being only .079 per cent. at ages 31-40, and as much as .564 per cent. at ages 61-70. Similar results connect themselves with the deaths from dropsy: but in the section "apoplexy," the greatest variation is observable in connection with a difference of age; at the term of life 31-40, the mortality is .062 per cent., increasing rapidly till ages 71-83, in which it is 1.436 per cent. from this disease. This is in accordance with the received opinion of medical men on the character of this disease.

If the influence of the above mentioned six groups of diseases be now viewed in connection with specific terms of life, it will be seen that, in the decennial period, 31-40, the greatest rate of mortality has taken place from "pulmonary diseases," next from "fevers," then from "local inflammations," "abdominal diseases," "apoplexy," and least of all from "dropsy;" and in the next ten years of life, the mortality of these diseases follows the same order as to their intensity. In the term of life 51-60, however, the following is the order in which the same six diseases stand as to intensity:—apoplexy, fever, pulmonary diseases, inflammation, dropsy, and abdominal diseases. And in the ten years 61-70, the order is again varied, being apoplexy, inflammation, abdominal diseases, fever and dropsy equal, and pulmonary diseases at the bottom of the scale; and in the most advanced term of life of the preceding Abstract, the following is the order of intensity of the diseases:—apoplexy, inflammation, fever, abdominal diseases, dropsy, and pulmonary diseases. The following arrangement may perhaps exhibit these results in a more simple form:—

*Diseases arranged according to the order of their Intensity at the following Terms of Life.*

| 31-40.              | 41-50.              | 51-60.              | 61-70.              | 71-83.              |
|---------------------|---------------------|---------------------|---------------------|---------------------|
| Pulmonary Diseases. | Pulmonary Diseases. | Apoplexy.           | Apoplexy.           | Apoplexy.           |
| Fevers.             | Fevers.             | Fevers.             | Inflammations.      | Inflammations.      |
| Inflammations.      | Inflammations.      | Pulmonary Diseases. | Abdominal Diseases. | Fevers.             |
| Abdominal Diseases. | Abdominal Diseases. | Inflammations.      | Fevers. }           | Abdominal Diseases. |
| Apoplexy.           | Apoplexy.           | Dropsy.             | Dropsy. }           | Dropsy.             |
| Dropsy.             | Dropsy.             | Abdominal Diseases. | Pulmonary Diseases. | Pulmonary Diseases. |

Pulmonary disease is, therefore, so far as the preceding facts are concerned, essentially the disease of highest intensity in the destruction of life under 50, and above that age, apoplexy; the other diseases maintaining varying but intermediate positions in the scale of mortality.

The preceding classification of diseases, although it is that given in the Reports referred to, is evidently not sufficiently exact in its arrangement to merit much further criticism on the results; and it has therefore been thought desirable to classify the deaths according to a better nosological system. The whole of the deaths for the eleven years 1839-49, have, therefore, been so classified: the facts given not admitting of the deaths in the first ten years being so treated. It will be seen, that during the eleven years 1839-49, there have been 2471 deaths, and in the ten years 1829-38, there have been 672 deaths, making in all 3143, so that nearly 79 per cent. of the whole become subject to the more complete nosological classification. The information furnished respecting each death, not only gives the age and cause of death, but also the age at the time the life was assured; in every instance distinguishing the ages to the nearest month, so that a new and

important element in vital statistics is thus introduced, by which can be seen the facility with which different diseases may engraft themselves on the constitution at different terms of life, or, in other words, the rate at which the deterioration of life takes place from the standard of ordinary health, at different ages, from various diseases; for, with respect to all the lives now under consideration, at the time the assurances were effected, they underwent the usual scrutiny before admission into the Society.

In the following Table will be found an abstract of the number of deaths which have taken place at the various periods of life from different diseases; at the same time setting forth the period which has elapsed, in years and months, from the date of effecting the policies to the date of death:—

## XII.

*Causes, and Total Duration of Life after Assurance.*

## AGE.

| 45—49. |           | 50—54. |           | 55—59. |           | 60—64. |           | 65—69. |           | 70—74. |           | 75—79. |           | 80—85. |           | All Ages. |           |

In this Table it will be found that the causes of death are unspecified in eight only out of the 2471 cases recorded. The results herein given are so novel, but yet so varied that it will be impossible to discuss them fully within the limits of this paper, and only the most obvious will therefore be brought under consideration. In Abstract C, preceding, it was seen that, measuring the period which elapsed from the date of effecting the policies to the date of death, the interval was less for young lives than for older ones; and here, by adopting the opposite test, of measuring the interval from the date of death to the date of assuring, the same law is found to prevail, although in a more remarkable degree; and this difference is evidently owing to the circumstance, that all deaths among policies of long standing must necessarily be included in the more advanced periods of life in Table XIII, but included in younger periods of life in Abstract C. However, as the same law shews itself in both classes of results, and differing only in degree, the

(continued).

Causes, and Average Duration.

greater weight is thereby given to the unexpected principles disclosed, and should lead those connected with the management of life offices to the serious consideration of the financial questions which so obviously arise out of the results. From the relatively high rate of mortality at the more advanced ages, than at the younger ages, among assured lives, compared with those of the community generally, an opinion almost universally prevails, that there must be a loss, instead of a profit, connected with the transactions on old lives, and in consequence a number of life offices will not assure the lives of old persons. But if the ratio of lapsed policies, as set forth in Table XV,—and the ratio is much higher in this country,—be viewed in connection with the most remarkable law disclosed in Abstract C and Table XIII, there can no longer be any doubt that the general opinion is a most fallacious one, and unfortunately prevails to the serious detriment of the older class of lives, to whom, in pecuniary transactions, the principles of life assurance

are more strictly applicable than any other. Apart from statistical evidence, it must be sufficiently obvious, on an attentive consideration of the doctrine of probabilities, that in guaranteeing any event connected with the law of averages, the nearer to unity the chances of the contingency taking place be, the less the hazard of any adventure on the result. And if to this general principle be added the incidental pecuniary advantages arising from the moral influences and considerations which bear on the prosperity of a life office, the absurdity of the prejudice which prevails against assuring old lives must immediately appear. The following shews the results for six of the principal classes of disease:—

#### ABSTRACT K.

*Average Period elapsed from the Date of Assuring to the Date of Death, among Persons Dying at the following Ages.—Gotha Life Office.*

| DISEASE.                                                                       | 25 to 29. |         | 30 to 34. |         | 35 to 39. |         | 40 to 44. |         | 45 to 49. |         | 50 to 54. |         | 55 to 59. |         | 60 to 64. |         | 65 to 69. |         | 70 to 74. |         | 75 to 79. |         | All Ages. |         |

| VII. Diseases of the Stomach, Liver, and other Organs of Respiration . . . . . | 2         | 3       | 3         | 9       | 5         | 8       | 7         | 8       | 6         | 11      | 9         | 8       | 10        | 9       | 10        | 3       | 12        | 4       | 15        | 8       | 17        | 10      | 9         | 1       |

Of the diseases in class I, namely, the zymotic diseases, it will be seen that the duration of the assurances on the lives falling by this class of disease, is less at every age than the average from all causes, except at the term of life 35–44; and it will likewise be seen, that for all ages taken collectively, the duration of the policies lapsing from these diseases is less than the average duration of all policies.

The same observation does not apply to class II. Under age 40, the duration of the policies is less than the average; but in the term of life 40–54, greater; the succeeding ten years again less; and in the term 65–74, greater; but for all ages collectively, the duration of policies becoming claims on account of death from this group of diseases, is five months' greater than the average.

In group III, which includes the tubercular diseases, it will be seen, that for all ages under 60, with the exception of the quinquennial term, 40–44, the period elapsed from the date of assuring to the date of death is above the average of the period connected with the deaths from all causes; shewing that, for those ages, the deaths of this class, which consists chiefly of phthisis, must be induced by a disease slow in its operation, and in that respect differing from the characteristic of group I. In respect to one term of life, 40–44, the deaths taking place therein, from this group of diseases, have followed very rapidly on the date of the lives being assured, and so remarkably so, as to reduce the average, at all ages collectively, from this disease, more than one year below the average from all causes. At the term of life 40–44, the period elapsed in the deaths from

all causes is 6 years 8 months, but in the group of tubercular diseases, it is only 4 years 8 months; and this would appear to be a true feature of the disease, for the greatest number of deaths have taken place at this term of life; at the other terms of life, when the opposite feature prevails, up to age 60, the result is constantly above the average. On referring to the details of group III, it will be found that these peculiar results are due wholly to the deaths from phthisis, and therefore the preceding observations are strictly applicable to that disease only.

Group IV contains the diseases of the nervous system, and it will be seen that the results do not differ widely from those for all causes; and the same remark applies to the deaths from apoplexy, which form a large proportion of this section.

On referring to group VI, which represents the other diseases of the lungs and of the organs of respiration, it will be seen that, with the exception of the decennial term of life, 55-64, the deaths take place in a shorter time after the date of assuring than in the average of the deaths from all causes, and in the aggregate of all the ages, the difference is six months. These results are due chiefly to the deaths from pneumonia, which constitute 229 out of the 251 deaths of this group. And it will further be seen, that the deaths from asthma have taken place at a period prolonged beyond the average.

In regard to the diseases enumerated in group VII, it will be found that, on the average, they agree in their results with the deaths from all causes; and that in the different quinquennial terms of life, the results are in some instances above, and in others below, the average.

If attention be now directed to the rate of mortality from the various specified causes given in Table XIII, it will be found that, for all ages taken collectively, the greatest mortality has resulted from zymotic diseases, or those forming group I; and next, tubercular diseases, or group III, which are here separated from the other diseases of the lungs and organs of respiration, which form a distinct class in group VI. The following Table is an abstract of the results in Table XIII, so far as concerns the rate of mortality; and it will be observed that the rate of mortality from the zymotic diseases does not differ widely between ages 31-50; but from that age upwards, a rapid and uniform rate of increase takes place:—In group II, including dropsy, cancer, &c., there is a uniform rate of increase from the younger to the older ages. In the class of tubercular diseases, there is not much difference in the rate of mortality between ages 31-50; but in the next three quinquennial terms of life, there is a gradual increase. In group IV, there will be observed a very great difference between the rate of mortality at the younger and more advanced ages; of the 375 deaths in this group, 274 consist of deaths from apoplexy, and the results are therefore conformable to those already described in connection with Table XI, preceding. The results of group VI resemble in their relation those in connection with group III. Group VII, it will be observed, resembles the results of group IV, in having a very low rate of mortality at the earlier ages, and increasing rapidly at the more advanced terms of life.

TABLE XIV, deduced from TABLE XIII.

The preceding remarks have been made on six only of the principal groups of diseases, and the following still more condensed Abstract of the results may be interesting. The Roman numerals represent the diseases as grouped in the preceding Table and in Table XIII.

*Diseases arranged according to the order of their Intensity at the following Ages.*

| 31—35.       | 36—40.    | 41—45.      | 46—50.    | 51—55.    | 56—60.      | 61—65.    | 66—70.     | 71—80.       |
|--------------|-----------|-------------|-----------|-----------|-------------|-----------|------------|--------------|
| I }<br>III } | I<br>III  | III<br>I    | I<br>III  | III<br>I  | I }<br>II } | II<br>IV  | IV<br>II   | II<br>IV     |
| II }<br>VI } | VI<br>IV  | II<br>IV }  | II<br>IV  | IV<br>II  | IV<br>III   | I<br>III  | I<br>VI    | I<br>VI }    |
| IV<br>VII    | II<br>VII | VI }<br>VII | VI<br>VII | VI<br>VII | VII<br>VI   | VII<br>VI | VII<br>III | VII }<br>III |

In the above, as in Table XI, it will be seen that, at the earlier ages, the intensity of the zymotic diseases, and also tubercular disease, is greatest; but at the more advanced, a gradual falling off will be observable in the class of tubercular disease. In the term of life 56–65, tubercular disease stands fourth in the order of intensity, and in the term 66–80, last in order. Again, with respect to class IV, which consists, to a great extent, of deaths from apoplexy, it will be observed that, in the period of life 36–50, it stands fourth in the order of intensity; but that in each of the three succeeding quinquennial terms of life it gradually advances one step in the order of intensity, until, at the term 66–70, it is highest in intensity. This assimilates strictly with the results at pp. 170, 171 preceding. The class of pulmonary diseases, however, or diseases of the respiratory organs, not only in Table XI, but in the Abstracts given in pages 169 and 171, as well as in the earlier Reports of the Registrar-General, included group III, and also group VI; and if the results be viewed in accordance with this arrangement, the diseases of the respiratory organs will be found to take precedence of all others between ages 31–70, and in the term of life 70–80, they will stand fourth in order.

With the view to shew the relative intensity of the various groups of disease at different terms of life amongst different populations, the following Abstracts, deduced from facts presented in the Reports of the Registrar-General, are given:—

## MORTALITY OF THE PROVIDENT CLASSES

## ABSTRACT L.

With respect to the results furnished in the preceding Abstracts, it may be sufficient to refer to those in connection with the term of life 41–50; and so far as concerns the group of zymotic diseases, it is obvious that the intensity of mortality is higher in the Gotha Life Office than in any of the other classes of facts brought forward; but in regard to group II, which includes dropsy, cancer, and diseases of uncertain seat,

the opposite result is observable, the mortality being less in the Gotha Life Office than in any of the other classes of facts now under observation ; but in respect to the diseases of the respiratory organs, the results for the same ages are very remarkable and important, being for the four different classes of facts, as follows, viz. :—

|                                 |                |
|---------------------------------|----------------|
| Gotha Life Office . . . . .     | ·419 per cent. |
| Division of East Kent . . . . . | ·520 ...       |
| Metropolis . . . . .            | ·962 ...       |
| Twenty-four Towns . . . . .     | ·989 ...       |

The immunity from this class of diseases in the Gotha Life Office, and also in the division of East Kent, is remarkable, when placed in contrast with the other figures. Similar remarks are applicable to the two other classes of diseases contained in the following condensed abstract of figures presented in the preceding Abstracts :—

| Group of Diseases, classified as in Table XIII. | Results per Cent.—Ages 41—50—for the different Classes of Disease in the |                        |             |                    |

| VII . . . . .                                   | ·095                                                                     | ·109                   | ·118        | ·143               |

The differences for other terms of life will be easily discovered from an examination of the various Abstracts.

With respect to the deaths which have taken place from Asiatic Cholera, it will be seen, from Abstract H, that 12 deaths took place from that cause in the ten years 1829–38, 17 in the ten years 1839–48, and 31 in the year 1849. In Table XI, it will be seen that, although the greatest number of deaths happened in the decennial term of life 41–50, still the highest rate of mortality from this disease was at ages 61–70 ; and if the results for the whole 21 years, as set forth in Table XIII, be considered in reference to age, it will be seen that the largest number of deaths have taken place between ages 51–60 ; but the rate of mortality has gone on increasing from the youngest to the oldest age, as will be seen by the following Abstract :—

| Age.       | Lives Exposed to Risk. | Deaths from Cholera. | Mortality per Cent. | Being One Death in |
|------------|------------------------|----------------------|---------------------|--------------------|
| 31 to 40   | 33,870                 | 7                    | ·021                | 4,762              |
| 41 ... 50  | 47,010                 | 15                   | ·032                | 3,125              |
| 51 ... 60  | 31,050                 | 18                   | ·058                | 1,724              |
| 61 ... 70  | 12,382                 | 17                   | ·137                | 730                |
| 71 ... 80  | 1,719                  | 3                    | ·175                | 571                |
| Total..... | 126,031                | 60                   | ·048                | 2,083              |

A similar law has always been observed elsewhere, although during epidemic periods the mortality must of course be greater than that shewn in the above Table. A few deaths took place at intervals throughout the whole period; but if the principal year of the epidemic be considered, namely, 1849, the rate of mortality will appear much increased:—

| Age.       | Lives Exposed to Risk. | Deaths from Cholera. | Mortality per Cent. | Being One Death in |
|------------|------------------------|----------------------|---------------------|--------------------|
| 31 to 40   | 3,565                  | 3                    | ·084                | 1,188              |
| 41 ... 50  | 5,766                  | 3                    | ·052                | 1,922              |
| 51 ... 60  | 3,060                  | 10                   | ·327                | 306                |
| 61 ... 70  | 1,653                  | 12                   | ·726                | 138                |
| 71 ... 80  | 341                    | 3                    | ·880                | 114                |
| Total..... | 14,385                 | 31                   | ·215                | 464                |

This will be found to be much under the rate of mortality from cholera in Paris and many other places during the year 1832, for all ages taken collectively; the result being one in 42·7 for Paris, but one in 464 in the Gotha Life Office, for ages 31–80. The influence of age is very remarkable in modifying the mortality from this disease. The following are the results for all ages in Paris, shewing the mortality from cholera from the 26th March to the 30th September, in the year 1832:—

| Age.       | Population. | Deaths from Cholera. | Mortality per Cent. | Being One in |
|------------|-------------|----------------------|---------------------|--------------|
| 0 to 5     | 53,124      | 1,311                | 2·468               | 41           |
| 5 ... 10   | 50,059      | 392                  | 783                 | 153          |
| 10 ... 15  | 54,696      | 202                  | 369                 | 271          |
| 15 ... 20  | 79,058      | 377                  | 477                 | 210          |
| 20 ... 25  | 82,044      | 959                  | 1·169               | 86           |
| 25 ... 30  | 75,836      | 1,206                | 1·590               | 63           |
| 30 ... 40  | 125,188     | 2,771                | 2·213               | 45           |
| 40 ... 50  | 97,526      | 3,727                | 2·796               | 36           |
| 50 ... 60  | 81,415      | 2,913                | 3·577               | 28           |
| 60 ... 70  | 58,625      | 3,121                | 5·324               | 19           |
| 70 ... 80  | 23,262      | 2,044                | 8·787               | 11           |
| 80 ... 90  | 4,715       | 365                  | 7·741               | 13           |
| 90 ... 100 | 314         | 14                   | 4·458               | 22           |
| Total..... | 785,862     | 18,402               | 2·342               | 42·7         |

The following is the rate of mortality from cholera, at corresponding ages, in the Gotha Life Office, Paris, and London:

| Age.     | Gotha Life Office, 1849. |        | Paris, 1832. |        | London, 1849. |        |
|----------|--------------------------|--------|--------------|--------|---------------|--------|
|          | Per Cent.                | One in | Per Cent.    | One in | Per Cent.     | One in |
| 31 to 40 | ·084                     | 1,186  | 2·213        | 45     | ·661          | 151    |
| 41 .. 50 | ·052                     | 1,922  | 2·796        | 36     | ·830          | 120    |
| 51 .. 60 | ·327                     | 306    | 3·577        | 28     | 1·243         | 80     |
| 61 .. 70 | ·726                     | 138    | 5·324        | 19     | 1·726         | 58     |
| 71 .. 80 | ·880                     | 114    | 8·787        | 11     | 2·182         | 46     |
| Total .. | ·215                     | 464    | 3·776        | 26     | ·962          | 104    |

Hence the mortality within the ages 31–80, is one in 464, while in Paris it was one in 26, and in London one in 104. The differences for each of the decennial periods of life are also shewn.

Abstract H, and Tables XI and XIII, will shew the mortality from violent causes. In the ten years, 1829–38, 11 deaths took place from suicide; in the twenty years, 1829–48, 64 deaths from the same cause; 39 of these deaths took place between ages 41–60. During the twenty-one years, 1829–49, 87 deaths took place from violent causes of all kinds, and an inspection of Section XVII of Table XIV, will shew the influence of age on the rate of mortality from these causes, and it will be found that with but slight irregularities, which appear to be due chiefly to small numbers, there is a gradual rate of increase from the younger to the older ages. In England and Wales, the deaths from violence, within the above ages, are one in 19; in the Equitable Life Office, one in 54; and in the Scottish Widows' Fund, one in 35; and in the Gotha Life Office, one in 28 of the total deaths, within the same term of life. This question will hereafter be more fully discussed.

Allusion has just been made to the mortality in the Scottish Widows' Fund and Life Assurance Society. In the "Monthly Journal of Medical Science" for January 1847, will be found a most interesting paper by James Begbie, M.D., Consulting Physician to the Society, on the Mortality of the Members. This is the only published document\* of any importance which gives the mortality from different causes amongst assured lives: the nosological arrangement of the return by the Equitable Society being so defective as to render the results of little or no practical value.

The facts brought under consideration by Dr. Begbie include the experience of the "Scottish Widows' Fund" for the years 1815–45, in which 642 deaths took place among 5989 persons, of whom 447 were females; but it is important to observe that all those persons whose policies were either surrendered or forfeited are not included in the preceding numbers, so that the full number of persons exposed to the risk of mortality in the

\* See also Table XX and Abstract S, which give the results of a further contribution by Dr. Begbie. Table XX likewise furnishes the general results of a similar investigation by Professor Christison.

Society, during the thirty-one years above referred to, is not given. There is another element of importance wanting in Dr. Begbie's paper. While the ages at death from different causes are furnished, the population for those ages, or the number of persons exposed to the risk of mortality at the corresponding terms of life is not given. It is greatly to be regretted that such is the case, for it deprives his paper of one of its most important uses. However, this defect might to some extent have been supplied from the distribution of ages in the Gotha Life Office, which cannot differ in any very marked manner from those in the Scottish Widows' Fund, had the gross numbers exposed to the risk of mortality also been given, and the surrendered and forfeited policies not been excluded. Notwithstanding these deficiencies, which will render a strict comparison with the results of the Gotha Life Office impossible, Dr. Begbie's paper is still full of interest, and should be studied by every one connected with the management of Life Offices, or giving attention to the more general question of Vital Statistics. It will be impossible within the limits assigned to the present contribution to do justice to the discussion into which Dr. Begbie enters on the results of his investigation: those who desire to follow him in those important details, must have recourse to the paper itself. The following exhibits the deaths from different causes, for all ages collectively, in the Gotha Life Office, and in the Scottish Widows' Fund Life Assurance Society.

## ABSTRACT O.

| CAUSE OF DEATH.                                    | Gotha Life Office. |                              | Scottish Widows' Fund. |                              |

In the above Abstract the relation of the two classes of facts is obvious, and calls for no further commentary; but it may be useful to give the results for each class of disease in the Scottish Widows' Fund according to age.

## ABSTRACT P.

| DISEASE.                                   | Ages at Death. |           |           |           |           |           |           | Total. |
|--------------------------------------------|----------------|-----------|-----------|-----------|-----------|-----------|-----------|--------|

In order that many of the preceding results may be clearly understood, it is necessary to direct attention to Tables XV and XVI, the former of which shews the progress of the Gotha Society, from 1829 to the end of the year 1849, and the latter shews the number and amount of assurances subsisting at the end of the year 1848.

TABLE XV.

*Number of Persons effecting Assurances during the Years 1829—49.*

| Year.  | Number of persons making new Proposals. | Number of persons effecting new Policies. | Gross number of persons Assured throughout the Year. | Persons on whose lives Policies were discontinued. |         |        | Persons on whose lives Policies were in force at the end of the Year. | Increase in the Year. | Average Age of the Assured. |         |
|--------|-----------------------------------------|-------------------------------------------|------------------------------------------------------|----------------------------------------------------|---------|--------|-----------------------------------------------------------------------|-----------------------|-----------------------------|---------|
|        |                                         |                                           |                                                      | Lapses.                                            | Deaths. | Total. |                                                                       |                       | Years.                      | Months. |

| Total. | 29,707                                  | 22,063                                    | 196,352                                              | 3,517                                              | 3,075   | 6,592  |                                                                       | 15,471                |                             |         |

The above will not correspond exactly in some of its details, particularly in relation to the number of deaths, with some of the preceding figures; in fact Table XV is a financial statement of the Society, and those conversant with the practical working of such institutions, will immediately understand the cause of such differences. The number of deaths which have actually taken place up to any given date being of necessity, in every large Society, greater than the payments made on account of deaths to the same date.

In the following Table will be found a statement of the number of assurances in the Gotha Life Office, subsisting on the 31st of December, 1848; to many persons the results may be interesting. The amounts assured are expressed in thalers, or rixdollars Prussian current, each being worth nearly three shillings sterling.

TABLE XVI.

*Assurances subsisting in 1848.*

In the preceding Table there is one feature of an unusual character, and of much practical importance to Life Offices, the ratio of lapsed policies to the gross number of policies effected. It will be seen that out of 22,063 persons whose lives were assured, the policies on the lives of 3517 were either surrendered, forfeited, or had expired; being about 16 per cent. of the whole. To those not familiar with the experience of Life Offices in this respect, the proportion may seem high: but it is very much below that of Life Offices in this country, and merits serious consideration on the part of those transacting assurance business on the Continent.

The following Abstract will shew the results for the Gotha Life Office, the Equitable Society of London, and the fifteen Life Offices reported on in 1843 by the Committee of Actuaries.

## ABSTRACT Q.

| Source of Data.         | Date of Experience.                                                   | Entrants. | Existing at the termination of Experience. |                          | Discontinued. |                          | Died.   |                          |

| Equitable Life Office.  | { 1762-1829, being 68 }<br>years .....                                | 21,398    | 6,930                                      | 32.4                     | 9,324         | 43.6                     | 5,144   | 24.0                     |
| Fifteen Life Offices. . | { 1772-1838, but chiefly }<br>from 1810-38, being }<br>29 years ..... | 40,616    | 25,462                                     | 62.7                     | 11,226        | 27.6                     | 3,928   | 9.7                      |
| Gotha Life Office. . .  | 1829-49, being 21 years ...                                           | 22,063    | 15,471                                     | 70.1                     | 3,517         | 16.0                     | 3,075   | 13.9                     |
| Combined Results...     | .....                                                                 | 84,077    | 47,863                                     | 56.9                     | 24,067        | 28.7                     | 12,147  | 14.4                     |

It is hence obvious that while the number of discontinued policies, being policies which have ceased to exist from all causes except death, is only about 16 per cent. of the original number of entrants in the Gotha Life Office, the ratio is as high as 43.6 per cent. in the Equitable, and even 27.6 per cent. in the fifteen Life Offices. It is to be regretted that the causes of discontinuance of the policies in each of those groups are unknown, but there is such a disparity in the results, that there can be very little doubt that a greater proportion of the policies issued on the Continent are kept in force for prudential reasons or family provisions, and that whether the increased ratio of discontinued policies in this country results from a greater proportion being originally effected for a temporary period only, still it is evident, from the fact of a less proportion of them being kept in force, that the prudential feelings among the assuring classes in Germany must be stronger than in this country.

The figures in the last column of Abstract Q, when viewed by themselves, can convey but little information, as the results are not derived from the number exposed to the risk of mortality, but from the original number of entrants, and consequently the rate of

mortality will depend on the ratio of discontinued policies, and the ages of the persons exposed to the risk of mortality.

In the following Abstract will be found the mortality per cent., without distinction of age, and the average duration of the assurances in each group of facts.

#### ABSTRACT R.

| Data.                   | Exposed to Risk. | Deaths. | Mortality per Cent. | Entrants. | Average Duration of each Policy. |
|-------------------------|------------------|---------|---------------------|-----------|----------------------------------|
| Equitable . . . . .     | 266,872          | 5,144   | 1.9                 | 21,398    | 12.5 years                       |
| Fifteen Offices . . . . | 220,787          | 3,928   | 1.8                 | 40,616    | 5.4 ...                          |
| Gotha Life Office . . . | 179,884          | 3,075   | 1.7                 | 22,063    | 8.1 ...                          |
| Total . . . . .         | 667,543          | 12,147  | 1.8                 | 84,077    | 7.9 ...                          |

The greater age of the Equitable Life Office destroys the value of any comparison between the results derived from the experience of that Society and either of the other sources of data; but a comparison may fairly be made between the results for the fifteen Life Offices and the Gotha Life Office. Fourteen of these Offices had on an average been established for eighteen years before the close of the experience here brought under review, and if the eldest office of the fifteen be included, the average duration of the term over which their transactions extend will not differ widely from that of the Gotha Life Office. This much being explained, it is certainly a very remarkable fact that the average duration of each policy effected in the English Life Offices should be less than five and a half years, and, in the Gotha Life Office, more than eight years. It is stated in the report by the Committee of Actuaries that, taking the whole of the data which they had under investigation, and which includes the above fifteen offices, and also the Equitable and Amicable Life Offices, the two oldest in existence, the average duration of all the policies is under eight years and a half. It is therefore evident that the interests of a Life Office, and particularly so in this country, are influenced by a great many other causes than simply the law of mortality prevailing among its members; and there is reason to believe that those disturbing causes will increase in intensity with the increased age and experience of the offices, and the gradual extension of the practice of Life Assurance among the population of this country.

In further illustration of this view the following analysis of the data furnished by the Committee of Actuaries, already referred to, will be of interest and importance to those connected with the management of life institutions. In order to construct Table XVII, it was necessary to make a very detailed analysis, shewing for policies effected at each quinquennium of age, the number of premiums received on each class of policies distinguished in the second, third, and fourth columns of the following Table.

The aggregate results so far as the policies in columns 3 and 4 are concerned is shewn in column 5. It is also necessary to explain that the amount assured by each policy was for the purpose of this illustration assumed to be £100, and that the scale of premiums payable under the policies was such as would be deduced from Table C, males, pp. 5-6 *ante*, calculated at 3 per cent. with a loading of 20 per cent.—a rate of premium which would be a fair average rate according to the present practice of life offices.

TABLE XVII

*Shewing the number of "Existing" and "Discontinued" Policies, the number of deaths which have taken place, and the ratio of the premiums which have been received on "Discontinued" Policies and Policies which have become "claims," to the sums paid on account of all the deaths which have happened.*

| Age when Assured. | Number of Policies. |                    |              |                                                | Amount of Premiums received on (c) = (d) | Sums paid for Deaths = (e) | Ratio of (d) to (e) | Age when Assured. |
|-------------------|---------------------|--------------------|--------------|------------------------------------------------|------------------------------------------|----------------------------|---------------------|-------------------|
|                   | Existing.           | Discontinued = (a) | Deaths = (b) | Number of Premiums received on (a) + (b) = (c) |                                          |                            |                     |                   |
|                   |                     |                    |              |                                                | £                                        | £                          |                     |                   |
| 1 to 5            | 10                  | 2                  |              | 7                                              | 10.50                                    |                            |                     | 1 to 5            |
| 6 ... 10          | 109                 | 48                 | 3            | 259                                            | 388.50                                   | 300                        | 129.500             | 6 ... 10          |
| 11 ... 15         | 207                 | 115                | 13           | 622                                            | 977.17                                   | 1300                       | 75.167              | 11 ... 15         |

| 66 ... 70         | 223                 | 98                 | 135          | 1102                                           | 11093.79                                 | 13500                      | 82.176              | 66 ... 70         |
| 71 ... 75         | 41                  | 24                 | 36           | 306                                            | 4048.37                                  | 3600                       | 112.455             | 71 ... 75         |
| 76 ... 80         | 6                   | 6                  | 4            | 45                                             | 795.96                                   | 400                        | 198.999             | 76 ... 80         |
| Total.....        | 25462               | 11226              | 3928         | 73203                                          | 271059 51                                | 392800                     | 69.012              | Total.            |

The ratios shewn in the 8th column of this Table will differ in some measure from the actual facts of the case, in consequence of fluctuations which may have taken place in the average of the amounts assured by "discontinued" policies, and by policies on which "claims" have arisen; and likewise in the disparity between the number of "short term" policies in the respective columns and those for the "whole of life"; but these objections will not in any serious way injure the practical value of the illustration furnished in the preceding Table.

It will be observed that between ages 26-60, the uniformity of the ratios in column 8, or the ratios of premiums received on the policies represented in columns 3 and 4, that is on discontinued policies of all sorts, to the amounts paid for claims, is very

remarkable: at the younger and older ages the numbers are small, and the results of course fluctuate. It thus appears that the premiums received on "discontinued" policies from all causes, death or otherwise, have, without any allowance being made for accumulation at interest, sufficed to meet 69·012 per cent. of the payments required on account of the deaths which have taken place. This is certainly a very striking fact when viewed in connection with the practice of life assurance, and will on reflection, after making full allowance for purchased or surrendered policies, be found to account to a very large extent for the enormous profits realised by some of the institutions from whose progress the preceding results are derived. It is not to be considered that the more recent experience of life offices is less remarkable: for as the practice of life assurance has gradually extended itself, the number of policies effected for purely prudential and family purposes is yearly becoming less and less in relation to the whole number effected; in consequence of the immense increase of assurances made on account of pecuniary arrangements of a temporary character. The future experience of Life Offices is, therefore, likely to exhibit results still more striking than those furnished in Table XVII.

It is obvious that in the process of constructing the preceding Tables, elements must have appeared by which it was easy to determine, from the experience of the fifteen offices now under consideration, the same class of facts as are exhibited for the Gotha Office in Abstract C, page 160 *ante*. The results of this part of the investigation will be found in the next Table.

TABLE XVIII.

*Period elapsed from the date of Assuring at various Ages till Death, of those dying among the Assured in the Fifteen Offices reported on by the Committee of Actuaries in 1843.*

| Age when Assured. | Number of Premiums received on each Policy. | Duration of Life. | Duration of Life to each Person. | Duration of Life. | Duration of Life to each Person. |
|-------------------|---------------------------------------------|-------------------|----------------------------------|-------------------|----------------------------------|

The results of this Table, although not shewing differences between the policies on young and old lives so marked as those in Abstract C, are still very remarkable; and strikingly corroborative of the operation of the principles which have been found to prevail in the Gotha Life Office. It will be seen that while in regard to the deaths which have taken place amongst persons assured at ages 21-30, the period which elapsed from the date of effecting the policy was 5.749 years, that which elapsed amongst those assuring in the decennium 41-50 was 6.736 years, the corresponding figures for the Gotha Office being 6.500 years and 9.750 years. After the observations which have been already made in pages 159-165, and also in pages 179-181, it is unnecessary to enlarge here on this part of the inquiry.

Before concluding the present contribution, it is necessary to state that, since I made the preceding investigation into the experience of the Gotha Life Office, Mr. Hopf, the Actuary of the Company, has published an able paper shewing the general results of the operations of the Society for the twenty-five years 1829-54, but not attempting to discuss the many curious and novel features which have arisen in this inquiry from the analysis of the data supplied by the annual reports of the Gotha Company. That the effect of the additional five years' experience on the preceding results may, however, be seen, the following Table is given, prepared on the model of Table XI, page 170 *ante*, from the facts furnished in Mr. Hopf's paper.

TABLE XIX.

| DISEASE.                                         | Ratio of Deaths from Different Causes during 1829 to 1854, at the following Ages. |                     |                |                     |                |                     |                |                     |                |                     |                |                     |                |                     |

The preceding results will not be found in any way to disturb the conclusions arrived at in the former part of this contribution; the rate of mortality, from the prolonged average duration of the policies and the consequent gradual disappearance of the effects of the original selection of the lives, being increased but to a very slight extent. The characteristic results of each class of disease is markedly similar to those already exhibited.

Since this investigation was originally made, Dr. Begbie has published another paper on the mortality which has taken place in the "Scottish Widows' Fund." It will be found in the "Monthly Journal of Medical Science" for August 1853, and includes the experience of the Society from its formation in 1815 to the close of the year 1852. In the same number of that publication will likewise be found a paper by Professor Christison, of Edinburgh, on the deaths which took place within the five years 1846-50 in the "Standard Assurance Company," of which he is the Medical Officer. Both papers are full of important and valuable information; and, as I have already remarked of Dr. Begbie's first paper, every one wishing to understand fully the contents of those now under consideration, must have recourse to the papers themselves; as it is here impossible to give more than such portions of the general results as bear directly on the questions already discussed in this contribution.

The following Table gives a succinct view of the three different classes of results:—

From the limited extent of the facts connected with the "Standard Life Office," extending over a period of five years only, and not including the whole experience of the

Company since its establishment in the year 1825, the results cannot be expected to assimilate closely to the other two classes of facts, but it will, nevertheless, be found that in some respects there is a remarkable agreement between them.

It is very interesting to observe, that between the results given for the Scottish Widows' Fund in Abstract O, based on 642 deaths only, there is an extraordinary agreement with those in the preceding Table, deduced from 1332 deaths in the same Society. It will also be observed, that the extended experience of this Society as now submitted shews almost the same relation to that of the Gotha Life Office as was formerly remarked; the deaths from diseases of the brain and the nervous system, from diseases of the heart and blood-vessels, from diseases of the organs of digestion, from diseases of the urinary organs, and from childbirth and diseases of the uterus, being in excess in the former, and the remaining classes of disease being in excess in the latter society; the relation being precisely that which was exhibited in Abstract O. This is a circumstance of some importance, and is well calculated to bestow confidence in the results of Dr. Begbie's inquiry.

It is, however, very deeply to be regretted that neither Dr. Begbie nor Professor Christison has been enabled to furnish the number of lives exposed to the risk of mortality at the corresponding ages at which the deaths are recorded to have taken place. This serious defect in the data of their papers deprives their investigations of much of their value, and every student of Vital Statistics must lament the absence of elements so essential to every exact inquiry. An inspection of the results presented in Tables XI, XII, XIII, XIV, and XIX, and in Abstracts H, K, L, M, and N, of this contribution, will confirm the more casual reader in this conclusion. In the absence of all information as to the number of lives exposed to the risk of mortality at different ages, the following Abstract is given that a comparison may be instituted between it and Abstract P, page 191.

## ON THE RATE OF MORTALITY AMONG PERSONS OF INTEMPERATE HABITS.

---

In the next place it is proposed to investigate the rate of mortality which prevails among persons addicted to the immoderate use of intoxicating drinks. Assurance companies have generally declined to assure such lives, from the supposed greater mortality to which they were believed to be subject; but no attempt has been previously made to test this opinion by properly authenticated facts; and it is therefore hoped that the data now brought under consideration may not be without interest. The results are calculated to throw considerable light on a question not only curious in itself, but evidently of much importance to Life Offices, as well as to the public generally.

The remarkable efforts which have been recently made to reform the drinking usages of society will be a sufficient apology for bringing under attention statistical evidences on a subject so deeply affecting the social, moral, and religious condition of the people.

It may be well to remark, that, in collecting the present data, the intention was to include in the observations only such persons as were decidedly addicted to drinking habits, and it was not intended to bring within observation mere occasional drinkers, or what is usually termed generous or "free livers." The reasons for this distinction will hereafter appear. It may also be stated, that the primary reason for collecting the facts was to apply the results to life assurance operations, and it was consequently important to include only well-marked cases of intemperance. Examination will shew that, for social and moral purposes, this would also have been the only satisfactory course to follow; but that the plan adopted for obtaining the present collection of facts may be the better understood, the following circular and schedule are given:—

Medical, Invalid, and General Life Office,  
25, Pall Mall, London.

SIR,

I beg to inclose you forms for the collection of cases of the mortality of persons of intemperate habits.

Many difficulties have been experienced in attempts to procure satisfactory data on the value of life among persons addicted to the excessive use of intoxicating drinks, and therefore the present method has been resorted to, in order to increase the information on the subject. May I solicit your assistance in filling up any portion of the inclosed schedules; and should your knowledge of cases be so extensive as to require more than the number sent, others will be forwarded on hearing from you to that effect. If you could also suggest any gentleman who would be useful in giving the information required, I would put myself in communication with him on the subject.

Hoping I may calculate on your co-operation, I beg to direct your attention to the subjoined hints on filling up the schedules.

I am, SIR, your most obedient Servant,  
F. G. P. NEISON, Actuary,

N.B.—No case should be entered in the schedule unless the person alluded to was decidedly addicted to drinking habits during a considerable period of life.

The peculiar feature of the intemperance, whether the favourite beverage was fermented or distilled liquors, should be stated in the column "Remarks," and also whether the intemperance continued to the time of death.

If the correct age at death be known, it will be entered as such; if not, the age must be guessed or approximated to by whoever fills up the schedule, or by the *mean age* of that guessed at by two or three persons who may have known the individual in question.

The name in full, or at least the initials of the person in question, and also the place of death, should be entered in the columns set apart for that purpose. This will be necessary, in order to correct double entries which may be made by two different persons.

In the column of the "Cause of Death," insert the post mortem examination, if practicable, such as diseases of the heart, liver, lungs, kidneys, &c., &c., (*and perhaps terminating in dropsy, &c., &c.*)

Please to return the schedules as soon as you have entered all the cases which have come under your observation.

*It is not expected that the schedules can be always filled from registers or notes kept for the purpose; but generally from a distinct recollection of the cases, and an approximation to the truth is therefore all that is calculated on being obtained.*

#### INTEMPERANCE.—SCHEDULE.

| Description.               |      |                           | Death.   |           |         | Disease or Cause of Death. | Duration of Intemperance. | Remarks on the Peculiar Features of the Intemperate Habits; whether they existed up to the period of Death, and any other Observations necessary. |
|----------------------------|------|---------------------------|----------|-----------|---------|----------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Name or other Distinction. | Sex. | Profession or Occupation. | Date of. | Place of. | Age at. |                            |                           |                                                                                                                                                   |
|                            |      |                           |          |           |         |                            |                           |                                                                                                                                                   |

It is obvious that it would be very difficult, if not impossible, to give such a definition of what constitutes intemperate habits as would be satisfactory to every one; almost every person would have a standard of his own by which to determine the fact of temperance or intemperance, and therefore in the preceding circular no attempt has been made to define the particular character of the habits on which information is sought; and all that has been urged on the attention of those filling up the schedules is to give only well-marked cases, and to include none but persons who were decidedly addicted to drinking habits. The consequence of following this course is, that the objections which might be urged against the adoption of any individual or peculiar test are avoided, for, by leaving it to each contributor of data to determine for himself what constitutes decidedly intemperate habits, the whole data taken collectively, from all the various contributors, will shew very precisely the result of those habits which the public, by common consent, admit to be intemperate; so that, however any individual reasoner on the results may argue, and whatever peculiar construction he may choose to put upon them, it will be impossible to avoid the conclusion, that the data really relate to what the public generally regard as persons of intemperate habits. If the testimony of those more advanced in life is to be fairly trusted on this subject, it must be admitted, that during the last quarter of a century, the drinking practices of society have much altered, and what is now commonly regarded

as free living, would have been looked upon some years since as only moderation; so, in like manner, may it be hoped that the usages of society will continue to improve, and, at no distant date, the habits now considered not to exceed the bounds of moderation be altogether unknown in polite and refined society. It is, therefore, possible that what has hitherto been regarded as intemperate habits, may differ very widely from that which may be looked upon as intemperance some years hence.

From the information obtained on these schedules, the following facts and results are derived; and it may here be stated that defective schedules have been completely rejected. For the mode by which the data have been analysed, reference may be made to the paper "on the Mortality of the Medical Profession," pp. 103-4 *ante*, and to that on the "Mortality of Master Mariners," pp. 134-137 *ante*. A similar plan has been followed in the present instance, and a careful perusal of those papers will make the method clearly understood, and shew how the facts have been brought into the form of the following Table:—

TABLE I.  
*Mortality among Persons of Intemperate Habits.*

| Age. | Number coming under Observation at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Died. | Half of Entered. | Number Exposed to Risk. | Age. | Number coming under Observation at each Age. | Number remaining under Observation from Age preceding. | Total Number under Observation at each Age. | Died. | Half of Entered. | Number Exposed to Risk. |

These curious and remarkable results exhibit a rate of mortality for which the most careful observers will be generally unprepared. When intemperate lives are occasionally accepted by Life Offices, the rates of premium charged by them fall greatly short of what would be indicated by the preceding figures; and it is to be feared that a careful examination of their experience must shew that the arbitrary mode by which such peculiar risks have been estimated has led them into unprofitable speculations. Throughout the whole range of the Table, it will be seen that the rate of mortality is frightfully high, and unequalled by the results of any other series of observations made on any class of the

population of this country. Sanitary agitators have frequently excited alarm about the wholesale havoc in human life going on in the badly-conditioned districts of some of our large cities; but no collection of facts ever brought under attention has shewn so appalling a waste of life as is exhibited by the above results.

From the age of sixteen upwards, it will be seen that the rate of mortality exceeds that of the general population of England and Wales. In the 6111·5 years of life to which the observations extend, 357 deaths have taken place; but if these lives had been subject to the same rate of mortality as the population generally, the number of deaths would have been only 110, or not quite 31 per cent. At the term of life 21–30, the mortality is upwards of five times that of the general community; and in the succeeding twenty years of life, it is above four times as great, the difference, as might be expected, gradually becoming less and less as age advances. If there be anything, therefore, in the usages of society calculated to destroy life, the most powerful is certainly the inordinate use of strong drink.

From the preceding data the following Tables have been constructed, in order to exhibit more clearly the rate at which persons of intemperate habits die, and consequently the average duration of their lives.

The principles on which the methods of calculation, here employed, depend, are precisely the same as those which regulated the formation of the Tables in pp. 117–120, 129, and 145–148.

But that these principles may be more clearly understood, and the resulting processes defined, it may be useful to furnish some explanation of the method of interpolation employed in this and the preceding contributions, as some persons may be anxious to understand the precise steps of the argument which have led to the adoption of the principles here followed. They will be found fully demonstrated in an article in the “*Connaissance des Temps pour l’an 1847*,” by M. Fred. Maurice. Their first application to Mortality Tables will be found in my Report on the Bengal Military Fund, in 1849.

In this extract we must assume that the reader is acquainted with the method of finding the successive orders of differences, and also with the elementary expressions in the calculus of operations. We shall here adopt the usual notation of successive differences, though, for practical reasons, the exponents are placed at the bottom of the symbols where we have had occasion to use them in the former part of this work.

The proposition which we have to consider is as follows:—

Having a series of terms given, of which the differences of a certain order are constant, it is required to find any number of intermediate terms following the same law.

The difficulty lies in finding the differences of the interpolated series so as to suit

all cases,—whatever the number of terms to be interpolated may be, and whatever order of differences may happen to be constant in the given series.

We assume that in all cases in which the series consists of rational and integral functions, when equidistant terms have a certain order of differences constant, the intermediate numbers, if also equidistant, will have the same order of differences constant. [The proof of this is given by M. Maurice, but it is omitted here for the sake of brevity.]

Let there be two series, in one of which all the terms are given, and in the other only every  $h^{\text{th}}$ ; thus,

$$\begin{array}{cccccccccccccccc} v & & v_1 & & v_2 & & v_3 & & v_4 & & v_5 & \dots & v_x \\ u, u_1 & u_2 & u_3 & \dots & u_h & u_{h+1} & u_{h+2} & u_{h+3} & \dots & u_{2h} & u_{h+1} & \dots & u_{3h} & \dots & u_{4h} & \dots & u_{5h} & \dots & u_{xh} \end{array}$$

It is evident that if  $v = u$  and  $v_1 = u_h$  we shall have in every case

$$v_x = u_{xh}$$

Then denoting the differences of  $v$  by  $\Delta$ , and those of  $u$  by  $\delta$ , we shall have

$$u_1 = u + \delta u, \quad v_1 = v + \Delta v = u + \Delta v$$

whence

$$\Delta v = v_1 - u = u_h - u,$$

consequently, since, by the ordinary expression in the calculus of differences,

$$u_h = (1 + \delta)^h \cdot u, \quad \text{we have}$$

$$\Delta v = \{(1 + \delta)^h - 1\} \cdot u$$

Also because

$$v_1 = (1 + \Delta) v = u_h = (1 + \delta)^h u,$$

$$\therefore (1 + \delta) \cdot u = (1 + \Delta)^{\frac{1}{h}} \cdot v$$

and because  $v = u$

$$\delta u = \{(1 + \Delta)^{\frac{1}{h}} - 1\} \cdot u$$

which becomes in its general form

$$\delta^m u = \{(1 + \Delta)^{\frac{1}{h}} - 1\}^m \cdot u \quad \dots \quad (A)$$

So when  $m = 1$ , we have

$$\delta u = \{(1 + \Delta)^{\frac{1}{h}} - 1\} u = \left\{ \frac{\Delta}{h} + \frac{1 \cdot 1 - h}{1 \cdot 2} \cdot \frac{\Delta^2}{h^2} + \frac{1 \cdot 1 - h \cdot 1 - 2h}{1 \cdot 2 \cdot 3} \cdot \frac{\Delta^3}{h^3} + \dots \right\} \cdot u$$

Now let us take  $h = 5$ , and suppose  $\Delta^4 u$  constant; and for shortness put  $\frac{\Delta}{5} = k$ ; the co-efficient of  $\frac{\Delta^2}{h^2} = a$ ; the co-efficient of  $\frac{\Delta^3}{h^3} = b$ ; &c.

$$(1) \quad \delta u = \{k + a k^2 + b k^3 + c k^4\} u.$$

Consequently  $\delta^2 u$  will depend on the square of this value of  $\delta u$ ; but, as we neglect the powers of  $k$  above the 4<sup>th</sup>, if we put  $k + a k^2 = p$ , and  $b k^3 + c k^4 = q$ , we see that in the development of  $\delta^2 u = (p + q)^2 u$  we have to regard only the expression

$$\delta^2 u = (p^2 + 2 p q) u,$$

which gives us, rejecting  $k^5$  and  $k^6$ ,

$$(2) \quad \delta^2 u = \{k^2 + 2 a k^3 + (a^2 + 2 b) k^4\} u$$

Similarly  $\delta^3 u = (p + q)^3 u$

$$= (p^3 + 3 p^2 q + \dots) u$$

or rejecting the higher powers of  $k$ ,

$$(3) \quad \delta^3 u = \{k^3 + 3 a k^4\} u$$

and

$$(4) \quad \delta^4 u = \{k^4\} u$$

The numerical co-efficients are easily found.

$$\frac{1.1 - h}{1.2} = \frac{1.(-4)}{1.2} = -2 = a$$

$$a \cdot \frac{1 - 2h}{3} = -2 \cdot \frac{-9}{3} = 6 = b$$

$$b \cdot \frac{1 - 3h}{4} = 6 \cdot \frac{-14}{4} = -21 = c$$

also

$$2 a = -4 \quad a^2 + 2 b = 16$$

$$3 a = -6$$

which gives us, restoring  $\frac{\Delta}{5}$ , for which we used  $k$ ,

$$\delta u = \frac{\Delta u}{5} - 2 \frac{\Delta^2 u}{5^2} + 6 \frac{\Delta^3 u}{5^3} - 21 \frac{\Delta^4 u}{5^4}$$

$$\delta^2 u = \frac{\Delta^2 u}{5^2} - 4 \frac{\Delta^3 u}{5^3} + 16 \frac{\Delta^4 u}{5^4}$$

$$\delta^3 u = \dots \frac{\Delta^3 u}{5^3} - 6 \frac{\Delta^4 u}{5^4}$$

$$\delta^4 u = \dots \frac{\Delta^4 u}{5^4}$$

It will be more simple first to apply this method of interpolation to cases in which we shall have integral results: to polygonal numbers, for instance, or to series of powers, as follows:—

Let it be required to interpolate 4 terms between each of the following, 816, 1771, 3276, 5456, 8436, 12341.

By a process exactly the same as is exhibited on page 145, we have

| $u$   | $\Delta u$ | $\Delta^2 u$ | $\Delta^3 u$ | $\Delta^4 u$ |
|-------|------------|--------------|--------------|--------------|
| 816   | 955        |              |              |              |
| 1771  | 1505       | 550          | 125          |              |
| 3276  | 2180       | 675          | 125          | 0            |
| 5456  | 2980       | 800          | 125          | 0            |
| 8436  | 3905       | 925          |              |              |
| 12341 |            |              |              |              |

Here then  $h=5$  and  $\Delta^3 u$  is constant;  $\Delta^4 u$  and all higher = 0.

$$\Delta u = 955 \quad \therefore \frac{\Delta u}{h} = 191$$

$$\Delta^2 u = 550 \quad \therefore \frac{\Delta^2 u}{h^2} = 22$$

$$\Delta^3 u = 125 \quad \therefore \frac{\Delta^3 u}{h^3} = 1$$

(where 191, 22, and 1 answer respectively to  $a$ ,  $b$ , and  $c$ , in the formula at the bottom of page 145).

$$\text{Consequently } \delta u = 191 - 2.22 + 6.1 + 0 = 153$$

$$\delta^2 u = 22 - 4.1 + 0 = 18$$

$$\delta^3 u = \dots\dots\dots 1 + 0 = 1$$

We are now prepared to proceed in finding the first four of the numbers required to be interpolated (compare with Abstract G, page 146).

| $u$  | $\delta u$ | $\delta^2 u$ | $\delta^3 u$ |
|------|------------|--------------|--------------|
| 816  |            |              |              |
| 969  | 153        | 18           |              |
| 1140 | 171        | 19           | 1            |
| 1330 | 190        | 20           | 1            |
| 1540 | 210        | 21           |              |
|      | 231        | 22           |              |
| 1771 | 253        |              |              |

In the next step we proceed in precisely the same way; only using the next series of differences, 1505, 675, 125, instead of 955, 550, 125. And in like manner of the rest. But as the third differences are constant the process of finding the succeeding terms may be carried on by simple addition.

But if we attempt to find the last four numbers required in the same manner as we found the first, we can no longer take the differences in the same order of position as before. We are compelled to go upwards, and to take as the  $\Delta u$  for interpolating between 8436 and 12341, the numbers 3905, 925, and 125.

Now, having inverted the direction in which we have taken the  $\Delta u$ , we must invert the numbers between which we propose to interpolate.

In this case  $\Delta u$  will be negative, and must be written  $-3905$ ;

$\Delta^2 u$  ... positive, and remains unaltered, 925;

$\Delta^3 u$  ... negative, and must be written  $-125$ ;

consequently  $\frac{\Delta u}{5} = -781$ ;  $\frac{\Delta^2 u}{5^2} = 37$ ;  $\frac{\Delta^3 u}{5^3} = -1$ .

Whence  $\delta u = -781 - 2.37 - 6.1 = -861$ .

$\delta^2 u = 37 + 4 = 41$

$\delta^3 u = -1 = -1$

3 H

And the last four of the required numbers are found as here shewn:—

| $u$          | $\delta u$ | $\delta^2 u$ | $\delta^3 u$ |
|--------------|------------|--------------|--------------|
| <b>12341</b> |            |              |              |
| 11480        | —861       | 41           | —1           |
| 10660        | —820       | 40           |              |
| 9880         | —780       | 39           |              |
| 9139         | —741       | 38           |              |
| 8436         | —703       |              |              |

We now give an example in which the differences are not constant till we reach a higher order,—the fifth. Let the given series be 32768, 161051, 537824, 1419857, 3200000, 6436343, and 11881376, to interpolate two terms between each.

$h=3$ , and  $\Delta^5 u$  is constant,

$$\text{Making } u = 32768, \Delta u = 128283 \therefore \frac{\Delta u}{3} = 42761$$

$$\Delta^2 u = 248490 \quad \frac{\Delta^2 u}{3^2} = 27610$$

$$\Delta^3 u = 256770 \quad \frac{\Delta^3 u}{3^3} = 9510$$

$$\Delta^4 u = 136080 \quad \frac{\Delta^4 u}{3^4} = 1680$$

$$\Delta^5 u = 29160 \quad \frac{\Delta^5 u}{3^5} = 120$$

Referring to Equation (A) above, page 206, and making  $m$  equal successively to 1, 2, 3, 4, and 5, we have, rejecting the powers of  $k$  above the 5th,

$$\delta u = \{k + a k^2 + b k^3 + c k^4 + d k^5\} u$$

$$\delta^2 u = \{k^2 + 2a k^3 + (a^2 + 2b) k^4 + 2(ab + c) k^5\} u$$

$$\delta^3 u = \{k^3 + 3a k^4 + 3(a^2 + b) k^5\} u$$

$$\delta^4 u = \{k^4 + 4a k^5\} u$$

$$\delta^5 u = \{k^5\} u$$

For the numerical co-efficients we obtain

$$\frac{1.1-h}{1.2} = -1 = a$$

$$a \cdot \frac{1-2h}{3} = (-1) \cdot \left(-\frac{5}{3}\right) = \frac{5}{3} = b$$

$$b \cdot \frac{1-3h}{4} = \frac{5}{3}(-2) = -\frac{10}{3} = c$$

$$c \cdot \frac{1-4h}{5} = \left(-\frac{10}{3}\right) \cdot \left(-\frac{11}{5}\right) = \frac{22}{3} = d.$$

$$2a = -2 \quad a^2 + 2b = 1 + \frac{10}{3} = \frac{13}{3} \quad 2(ab + c) = -10$$

$$3a = -3 \quad 3(a^2 + b) = 3\left(1 + \frac{5}{3}\right) = 8$$

$$4a = -4.$$

In this case, the formula at the bottom of page 143 no longer serves us; first, because we have to interpolate two terms instead of five, which changes the co-efficients, and secondly, because the differences are carried farther, giving more steps in the process.

Putting  $\frac{\Delta u}{h} = a$ ,  $\frac{\Delta^2 u}{h^2} = b$ ,  $\frac{\Delta^3 u}{h^3} = c$ ,  $\frac{\Delta^4 u}{h^4} = d$ , and  $\frac{\Delta^5 u}{h^5} = e$ , the formula for the present case is:—

$$\delta u = a - b + \frac{5}{3}c - \frac{10}{3}d + \frac{22}{3}e = 26281$$

$$\delta^2 u = b - 2c + \frac{13}{3}d - 10e = 14670$$

$$\delta^3 u = c - 3d + 8e = 5430$$

$$\delta^4 u = d - 4e = 1200$$

$$\delta^5 u = e = 120$$

Whence the terms succeeding 32768 are 59049 and 100000, and we have the power of continuing the series as far as may be necessary; the successive differences being formed by simple addition.

In applying this method to the interpolation of mortality, it must be observed that in such investigations we very rarely, if ever, meet with any order of differences constant, or even the same for two successive periods. The differences generally vary for every period for which we have to interpolate, and it is assumed that the second or third or other difference, as the case may be, is constant during the period of two, three, or five years, to which we are for the time being paying attention. Every separate period requires its own particular calculation, because the process cannot be carried on as in the instances given above, without a fresh calculation of  $\delta u$ ,  $\delta^2 u$ ,  $\delta^3 u$ , &c.

In consequence of the assumption that the differences of a certain order are constant, when in strict correctness they are not, the method of calculation by inverted differences as described above (pp. 209-10) is sometimes adopted, and found to produce greater verisimilitude. The ordinary procedure is generally preferable, but frequently there is special reason foremploying the other.

The following shews how easily the method is applied to various cases:—

Suppose we have to interpolate six terms, fourth differences being constant.

$$a = \frac{\Delta u}{7}; \quad b = \frac{\Delta^2 u}{7^2}; \quad c = \frac{\Delta^3 u}{7^3}; \quad d = \frac{\Delta^4 u}{7^4}; \text{—}$$

$$\delta u = a - 3b + 13c - 65d$$

$$\delta^2 u = \quad b - 6c + 35d$$

$$\delta^3 u = \quad \quad c - 9d$$

$$\delta^4 u = \quad \quad \quad d$$

If the third differences are constant the fourth are 0: in that case  $65d$ , and the terms that stand below it  $= 0$ , and are neglected.

This explanation will, it is hoped, render the method of interpolation adopted in this volume quite intelligible.

The construction of Table III depends on the following principles:—

If, at a given age,  $d$  be the mortality per cent.,  $\frac{d}{100}$  is the probability of the death of a single individual. The sum of the probabilities of two incompatible events  $= 1$ . Consequently the probability of any individual of the given age living for a year longer is  $1 - \frac{d}{100}$ . Similarly with regard to the mortality and probability at any other age.

Let  $d_m, d_{m+1}, d_{m+2}, \dots, d_{m+x}$  represent the mortality per cent. at the ages  $m, m+1, m+2, \&c.$  up to  $m+x$ : and let  $l_m$  denote the number living at the age  $m$ , and  $l_{m+x}$  the number living at the age  $m+x$ , then

$$l_{m+x} = l_m \left(1 - \frac{d_m}{100}\right) \cdot \left(1 - \frac{d_{m+1}}{100}\right) \cdot \left(1 - \frac{d_{m+2}}{100}\right) \cdot \dots \cdot \left(1 - \frac{d_{m+x-1}}{100}\right)$$

Make  $m$  the initial age of the Table; and let  $l_m$  be the radix (in this Table  $l_m = 100,000$ ): the numbers living at each successive age are found by the process just given. The numbers of intemperate persons living at any specified age, are, on the average and in the long run, the same proportion of the number that enter on the destructive habit, as the number opposite the age in column 4 of this Table is of 100,000.

TABLE II.

*Interpolation of Mortality per Cent.*

$$\text{Interval} = \frac{1}{5}.$$

(1) = Original Quantities.

$\Delta_1$  and  $\Delta_2$  = 1st and 2nd Differences.

$$a = .2 \Delta_1$$

$$b = .04 \Delta_2$$

| Age. | (1.)   | $\Delta_1$    | $\Delta_2$     |
|------|--------|---------------|----------------|
| 16   | 1.342  | + 3.611       | - 3.944        |
|      |        | + .7222 = $a$ | - .15776 = $b$ |
| 26   | 4.953  | - .333        | + 1.705        |
|      |        | - .0666       | + .06820       |

By an inspection of the figures in Table IV which is derived from Table III, it will be seen that an intemperate person of age 20 has an equal chance of living 15.6 years ; while a person of the general population of the country at the same age has an equal chance of living 44.2 years longer. Again, at age 30, the intemperate person has an equal chance of 13.8 years, and the other of 36.5 years. Also, at age 40, the chance of the one is 11.6 years, and of the other 28.8 years. The following will shew the results at different ages:—

TABLE IV.

*Equation of Life, being the Period of Years of which there is an equal chance of living, among the*

| Ages. | General Population,<br>England and Wales. | Persons of Intemperate Habits. |                                                                 |
|-------|-------------------------------------------|--------------------------------|-----------------------------------------------------------------|
| 20    | 44.212                                    | 15.557, being 35 per cent.     | } of the dura-<br>tion of life in<br>the general<br>population. |
| 30    | 36.482                                    | 13.800, ... 38 ...             |                                                                 |
| 40    | 28.790                                    | 11.627, ... 40 ...             |                                                                 |
| 50    | 21.255                                    | 10.860, ... 51 ...             |                                                                 |
| 60    | 14.285                                    | 8.947, ... 63 ...              |                                                                 |

It would be curious to contrast with the above results the rate of mortality among persons who have been for a considerable period of years, or for the whole of life, abstainers from intoxicating drinks; but, unfortunately, there are no available data connected with this class of lives, and it seems there will long be considerable difficulty in procuring such information. A few years ago, Mr. Munro, of Enfield, at much trouble and expense, procured returns from Rechabite societies, shewing the rate of mortality and sickness experienced by the members, and it is known that the results, although not published, exhibit as high a rate of mortality and sickness as is found to prevail among the members of other friendly societies. The facts collected by Mr. Munro are of great value, and it is to be regretted that the societies furnishing them should, on account of the unfavourable nature of the results arrived at, object to their publication. For, although they shew a high rate of mortality, it should be kept in view that all the members cannot yet be fairly considered as the type of genuine abstainers; many of them are reformed drunkards, and, as such, have become teetotallers, with broken-down constitutions. It may therefore be justly stated, that until Rechabite societies have enrolled a class of members who have been abstainers from infancy, they cannot expect an entire immunity from those diseases and deteriorating influences on health to which less careful members of the community are subject.

In a most valuable paper read before the Statistical Society by Colonel Sykes, in the year 1851, will be found some remarkable facts as to the influence of intemperance on the sickness and mortality of European troops in the Madras presidency. Mr. Balfour, in his paper on Cholera, also gives some striking examples of the same class of results.

The facts collected in the preceding Schedule required an enumeration of the peculiar features of the intemperance in respect to the favourite beverage; and it is curious to remark the influence of the different kinds of drink on the duration of life.

The average duration of life, after the commencement of the intemperate habits, is,

|                                                                    |             |
|--------------------------------------------------------------------|-------------|
| Among beer drinkers . . . . .                                      | 21·7 years. |
| ... spirit drinkers . . . . .                                      | 16·7 ...    |
| And among those who drink both spirits and beer indiscriminately . | 16·1 ...    |

and, consequently, the rate of mortality will be,

|                               |                         |
|-------------------------------|-------------------------|
| Among beer drinkers . . . . . | 4·597 per cent. yearly. |
| ... spirit drinkers . . . . . | 5·996 ...               |
| ... mixed drinkers . . . . .  | 6·194 ...               |

Intemperate indulgence in the use of distilled liquors is hence more hurtful to health than the like use of fermented liquors, but the immoderate use of both combined is more injurious than the exclusive use of the one kind only.

These results are, however, not more curious than those connected with the different classes of persons.

The following shews the average duration of life, after the commencement of intemperate habits, among different classes of persons, namely:—

Among mechanics, working and labouring men . . . 18 years.  
 ... traders, dealers, and merchants . . . . . 17 ...  
 ... professional men and gentlemen . . . . . 15 ...  
 ... females . . . . . 14 ...

Among the general population, the distinction observable between the first two and the third of the classes is also known to exist, and the more regular and active physical exercises to which the members of the first two groups are subject, are very probably to a great extent the cause of the difference not only among the general population, but also among the intemperate persons now under observation.

It is obvious that none of the public records of this country connected with the hospitals or other public institutions, nor the returns of the Registrar-General, afford any means of knowing or ascertaining the number of deaths which take place from the use of intoxicating drinks. It is believed, that the present materials furnish better evidence on this question than anything else extant. In the returns of the Registrar-General, the nosological system adopted indicates what were the habits of the persons whose deaths are recorded in two instances only, namely, when the immediate cause of death appears under the term *delirium tremens*, or *intemperance*. It is, therefore, evident that those must embrace but a very small number of the deaths which actually take place among persons addicted to intemperate habits.

The following Table shews the deaths which happened from different causes among the facts now collected:—

TABLE V.  
*Immediate Cause of Death.*

| Immediate Cause of Death.   | Number of Deaths at the following Ages: |           |           |           |           |           |           |           |           |           |           |           |           |           |           |
|-----------------------------|-----------------------------------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
|                             | 16 to 20.                               | 21 to 25. | 26 to 30. | 31 to 35. | 36 to 40. | 41 to 45. | 46 to 50. | 51 to 55. | 56 to 60. | 61 to 65. | 66 to 70. | 71 to 75. | 76 to 80. | 81 to 85. | 86 to 90. |

From which it appears that the greatest number of deaths took place from Head diseases (Nervous system), namely, 97, of which 57 are recorded under the term "delirium tremens." The next in order are Disease of the liver, Dropsy, &c., and nearly the same number from Diseases of the respiratory organs. These results are rather curious, as shewing the very marked influence which intemperate habits have on the cause of death. Among the population of England and Wales, aged 20 and upwards, the deaths from Head diseases (Nervous System) constitute only 9.710 per cent. of the deaths from all causes at those ages; but among the intemperate classes they constitute 27.100 per cent., being nearly three times as great. With other diseases, similar differences will be found. In the general community, the deaths from Diseases of the respiratory organs, at the same periods of life, amount to 33.150 per cent. of the deaths from all causes; while among the intemperate group they are only 22.980 per cent. of all the deaths. The following figures exhibit these relations for England and Wales, for the Gotha Life Office, the "Scottish Widows' Fund" and the "Standard Assurance Company," (the last three being select classes, the details of which will be found in the preceding contribution), and also for intemperate lives.

## ABSTRACT C.

*Ratio per Cent. of Deaths, at ages 20 and upwards, from different causes, to the Total Deaths, from all causes, at the corresponding ages, in*

| Cause of Death.                  | England and Wales, 1847. | Gotha Life Office. 1839-49. | Scottish Widows' Fund. 1815-52. | Standard Life Office. 1846-50. | Intemperate Lives. |
|----------------------------------|--------------------------|-----------------------------|---------------------------------|--------------------------------|--------------------|
| Head diseases . . . . .          | 9·710                    | 15·176                      | 21·246                          | 18·089                         | 27·10              |
| Digestive organs . . . . .       | 6·240                    | 8·377                       | 12·838                          | 11·945                         | 23·30              |
| Respiratory organs . . . . .     | 33·150                   | 27·843                      | 21·096                          | 22·867                         | 22·98              |
| Total of the above three classes | 49·100                   | 51·396                      | 55·180                          | 52·901                         | 73·38              |

In England and Wales, the above three groups of diseases constitute 49·100 per cent. of the whole deaths; but in the intemperate class of lives they form 73·38 per cent. The most remarkable peculiarity in this respect is, however, the excessive development among intemperate persons of diseases of the Nervous system and of the Digestive organs. In England and Wales, these two groups form 15·950 per cent. of the deaths from all causes at the corresponding ages; but amongst intemperate persons, they form 50·40 per cent. of all the deaths which take place, or more than three times the general average. These may, therefore, be regarded as the distinctive type of the causes of death among intemperate persons; and the predominance of deaths assigned to such causes in any particular collection of facts, may fairly, in the absence of other and more direct evidence, lead to the inference of irregularity of habits having prevailed to an unusual extent. An inspection of the results given for the "Scottish Widows' Fund" immediately strikes the attention with the marked characteristics of this circumstance; there is an excess of the diseases of the Nervous system and Digestive organs, and a diminution of those of the Respiratory organs, being the same features, although not developed in so marked a degree, which are observable in the decidedly intemperate group of lives. The following shews that the results for the "Standard Life Office," but more particularly for the "Scottish Widows' Fund," hold something like an intermediate place between those for England and Wales generally, and the "intemperate group:"—

## ABSTRACT D.

| Group of Facts.                 | Ratio per Cent. to Total Deaths of Deaths from Diseases of the |                     |
|---------------------------------|----------------------------------------------------------------|---------------------|
|                                 | Nervous System and Digestive Organs.                           | Respiratory Organs. |
| England and Wales . . . . .     | 15·950 per cent.                                               | 33·150 per cent.    |
| Standard Life Office . . . . .  | 30·034 ...                                                     | 22·867 ...          |
| Scottish Widows' Fund . . . . . | 34·084 ...                                                     | 21·096 ...          |
| Intemperate Lives . . . . .     | 50·400 ...                                                     | 22·980 ...          |

Dr. Begbie, in his interesting report on the mortality of the "Scottish Widows' Fund," although alluding to the fact that several of the persons who died from diseases of the digestive organs were reported "free livers," still seems not to have been impressed with the remarkably high ratio of deaths from this cause in the materials before him: and the same observation applies to Professor Christison's paper.

It has been said that the returns of the Registrar-General do not afford the means of determining the number of deaths which take place in this country from the use of intoxicating drinks; but if viewed in connection with the data brought forward in this paper, it is obvious that a means is now supplied of making a near approximation to the results required: and, with this view, attention is directed to the following Table:—

TABLE VI.

*Deaths in England and Wales, 1847, from*

| Age.      | Delirium Tremens. |          |       | Intemperance. |          |       | Both.  |          |       | All Causes. |          |         |
|-----------|-------------------|----------|-------|---------------|----------|-------|--------|----------|-------|-------------|----------|---------|
|           | Males.            | Females. | Both. | Males.        | Females. | Both. | Males. | Females. | Both. | Males.      | Females. | Both.   |

| 41 ... 50 | 131               | 18       | 149   | 46            | 17       | 63    | 177    | 35       | 212   | 14,044      | 13,379   | 27,423  |
| 51 ... 60 | 43                | 4        | 47    | 43            | 17       | 60    | 86     | 21       | 107   | 14,596      | 13,666   | 28,262  |
| 61 ... 70 | 26                | 6        | 32    | 23            | 6        | 29    | 49     | 12       | 61    | 17,923      | 18,048   | 35,971  |
| 71 ... 80 | 9                 | 1        | 10    | 5             | 1        | 6     | 14     | 2        | 16    | 19,292      | 21,334   | 40,626  |
| 81 ... 90 | 1                 | 1        | 2     | ...           | 1        | 1     | 1      | 2        | 3     | 10,138      | 12,179   | 22,317  |
|           | 424               | 52       | 476   | 184           | 71       | 255   | 608    | 123      | 731   | 111,524     | 117,256  | 228,780 |

The deaths recorded "delirium tremens" and "intemperance," as will be seen on referring to Abstract B, preceding, constitute but a small portion of the total deaths taking place among persons addicted to intemperate habits; and the following Table is prepared to shew the rate of mortality for each sex and term of life in England and Wales from those two specified causes:—

TABLE VII.

The following Abstract of this Table shews the relation of mortality in the sexes from those causes:—viz. when “delirium tremens,” or “intemperance” is recorded as the immediate cause of death.

ABSTRACT E.

| Age.      | Mortality per Cent. from Delirium Tremens and specified Intemperance, amongst |                |                                             |

| 71 ... 80 | .00826                                                                        | .00100         | 12 ...                                      |

The figures in the last column shew that the mortality of the female sex is, on an average, about one-fifth of that of the males, varying from 23 per cent. at age 21-30, to 12 per cent. at age 71-80. It will likewise be seen that the maximum rate of mortality in both sexes is at the term of life 41-50 gradually increasing from the younger ages to that period, and then decreasing to the more advanced ages. The above rate of mortality must not be confounded with that given in Abstract A, which shewed, as is usual in tables of mortality, an increasing rate from the younger to the older ages. There is an important distinction between the two classes of facts. Abstract A shews the rate of mortality among a class of people all of whom have indulged in the immoderate use of intoxicating drinks, while the facts given immediately above shew the proportion of deaths from certain forms of intemperance in the community generally at the respective terms of life; and although it be true that the rate of mortality is higher in the decade 41-50, it is not to be inferred that intemperate habits have the most detrimental effect on the constitution at those ages, for Abstract A proves that as age increases, the baneful influence on health of strong drinks also increases; the legitimate inference to be drawn is, simply, that drinking habits are more prevalent at that term of life than at any other; in fact, the figures just given demonstrate that the folly of indulging in the intemperate use of strong drinks grows on the community from youth to the mature period of manhood, 41-50 years of age, after which time the man gets sobered into the more limited use of them, avoiding the excesses of earlier years.

But perhaps the most curious circumstance disclosed by the above figures is the remarkable similarity between the proportion of crime in the sexes to the proportion of deaths from assigned causes of intemperance. By referring to a subsequent contribution shewing the influence of age on the development of crime, it will be found that the tendency to crime in the male sex is nearly five times as great as in the female sex, or, more strictly, in the relation of 336 to 1581; while the ratio of deaths to the population from assigned intemperate causes, at age 20 and upwards, are in the exact relation 8011 to 36,769, a most remarkable agreement, the difference being under 2.5 per cent.; 7814 substituted for 8011 would give the precise relation of the figures shewing the tendency of crime in the sexes. This is rather a strange coincidence, to be hereafter referred to more in detail; and may be probably viewed by most careful observers as proving that crime legally considered, and intemperance in its ordinary acceptation, are the concomitants of each other.

So far the deaths from intemperate habits have been spoken of in regard to the general population of England and Wales, as recorded under assigned causes in the reports of the Registrar-General; but it must be evident that the deaths actually occasioned, or, at all events, hastened, by extreme indulgence in intoxicating liquors, far exceeds those nominally recorded in the official returns as proceeding from this cause. This is satisfactorily proved by the facts in Table V and Abstract B. And, assuming that in the country generally the deaths in the Registrar-General's returns from intemperance would bear the

same relation to those under assigned causes, which the more careful observation of the facts analysed in Abstract B shews, it becomes a very easy matter to determine the number and ratio of deaths which actually take place among intemperate persons in England and Wales. On this hypothesis the following Table has been constructed: the numbers in the second and sixth columns consist of the product of the numbers in the lowest horizontal line of Abstract B, page 221, and the numbers for the corresponding ages in columns 8 and 9 of Table VI, page 223.

TABLE VIII.  
*Intemperance—England and Wales, 1847.*

In the above results, shewing the ratio of deaths as resulting from all intemperate causes, it will be observed that the maximum mortality takes place ten years later in life than in the results given in Table VII, and subsequent Abstract. This difference is due to the reduced ratio of deaths from delirium tremens at ages 51–60, in Abstract B; but,

notwithstanding this, it will be found that the relation of mortality in the male and female population is nearly as 5 to 1;—being as 7259 to 1421.

The following Table exhibits the rate of mortality in the whole population of England and Wales for the year 1847, being the period to which the facts already discussed in regard to intemperance relate. In page 4, *ante* Table B, will be found the rate of mortality for England and Wales for the years 1838–41, and a comparison will shew the increased mortality in the more recent year to be very considerable:—

TABLE IX.

The following Abstract gives the relation of the rate of mortality from intemperance to that from all causes for different terms of life:—

| Age.      | Mortality per Cent. from |          |               |          | Ratio of the Deaths from Intemperance to those from all causes. |                   |                   |                   |
|-----------|--------------------------|----------|---------------|----------|-----------------------------------------------------------------|-------------------|-------------------|-------------------|
|           | All Causes, 1847.        |          | Intemperance. |          | Males.                                                          |                   | Females.          |                   |
|           | Males.                   | Females. | Males.        | Females. | Per Cent. or 1 in                                               | Per Cent. or 1 in | Per Cent. or 1 in | Per Cent. or 1 in |
| 21 ... 30 | 1.016                    | .984     | .0281         | .0066    | 2.8 36                                                          | .7 149            |                   |                   |
| 31 ... 40 | 1.197                    | 1.286    | .0575         | .0085    | 4.8 21                                                          | .7 151            |                   |                   |
| 41 ... 50 | 1.708                    | 1.570    | .1055         | .0202    | 6.2 16                                                          | 1.3 78            |                   |                   |
| 51 ... 60 | 2.731                    | 2.378    | .1246         | .0284    | 4.5 22                                                          | 1.2 84            |                   |                   |
| 61 ... 70 | 5.111                    | 4.517    | .1241         | .0268    | 2.4 41                                                          | .6 168            |                   |                   |
| 71 ... 80 | 11.385                   | 10.701   | .0826         | .0100    | .7 138                                                          | .09 1,070         |                   |                   |

From the figures in columns 2 and 6 of Table VIII, it will be seen that, among persons addicted to decidedly intoxicating habits, 3182 males and 671 females die yearly, or 3853 of both sexes. This is strangely at variance with the statements put forth by some of the reformation societies, which make the number to be 50,000 yearly, or

upwards of one in 4 of the whole deaths at the corresponding ages of the deaths from all causes.

As the process is a simple one, it may be interesting before concluding this paper to make an estimate of the persons of each sex in England and Wales who are addicted to such habits of intemperance as will ultimately bring them within the preceding catalogue of deaths. If

$\delta$  = the number of deaths yearly taking place from intemperance in the corrected results of the returns of the Registrar-General, as given in Table VIII; and

$\pi$  = the mortality per cent. among persons of known intemperate habits, as given in Abstract A, page 204;

then  $\frac{100\delta}{\pi}$  = the existing number of drunkards, or persons given to extreme drinking usages.

On this principle, the following Table has been constructed:—

TABLE X.  
*England and Wales, 1847.*

| Age.      | MALES.                                  |                                 |            |        | Existing Number of Drunkards. |
|-----------|-----------------------------------------|---------------------------------|------------|--------|-------------------------------|
|           | Number of Deaths from Intemperance. (1) | $\lambda ((1) \times 100). (3)$ | (3) — (4). |        |                               |
|           | Mortality per Cent. (2)                 | $\lambda (2). (4)$              |            |        |                               |
| 21 to 30  | 428                                     | 4.6314438                       | 3.9365755  | 8,641  |                               |
|           | 4.953                                   | 0.6948683                       |            |        |                               |
| 31 ... 40 | 646                                     | 4.8102325                       | 4.1455905  | 13,983 |                               |

|           |                                         |                                 |            | 11,223                        | 64,806                        |

From which it appears that the number of

drunkards is { Males . . 53,583  
Females . 11,223  
Total . 64,806

which gives one drunkard to every 74 of the male population,

one ... 434 of the female population,

and one ... 145 of both sexes above the age of 20.

On the same principle the following gives the ratio of drunkards at each term of life:—

TABLE XI.

| Age.      | MALES.               |            |                                      |         | FEMALES.             |            |                                      |         |
|-----------|----------------------|------------|--------------------------------------|---------|----------------------|------------|--------------------------------------|---------|
|           | Population,<br>1847. | Drunkards. | Ratio of Drunkards<br>to Population. |         | Population,<br>1847. | Drunkards. | Ratio of Drunkards<br>to Population. |         |
|           |                      |            | Per Cent.                            | or 1 in |                      |            | Per Cent.                            | or 1 in |
| 21 to 30  | 1,521,610            | 8,641      | ·57                                  | 176     | 1,677,442            | 2,221      | ·13                                  | 755     |
| 31 ... 40 | 1,124,308            | 13,983     | 1·25                                 | 80      | 1,167,477            | 2,143      | ·18                                  | 545     |
| 41 ... 50 | 822,161              | 14,469     | 1·75                                 | 57      | 852,367              | 2,870      | ·34                                  | 297     |
| 51 ... 60 | 534,419              | 10,377     | 1·92                                 | 52      | 574,672              | 2,540      | ·44                                  | 226     |
| 61 ... 70 | 350,649              | 5,443      | 1·56                                 | 64      | 399,580              | 1,339      | ·34                                  | 298     |
| 71 ... 80 | 169,447              | 670        | ·40                                  | 253     | 199,368              | 110        | ·055                                 | 1,812   |

On giving close attention to the principles on which the two preceding Tables are constructed, it must be evident that the figures therein determined simply represent the class of persons in England and Wales who are included in the description given in the concluding paragraph of page 202 *ante*, and the numbers above are therefore not applicable to any other test of what constitutes Intemperance. No doubt there are many persons who will be found to maintain that the number of drunkards must be much greater than has been deduced in the foregoing calculations, but on reflection it will be found impossible for them to do so unless by the adoption of a much more severe test than it was thought proper to adopt for the purpose of this inquiry.

It is hoped that the facts contained in this Contribution may throw some light on a question not hitherto investigated statistically; and that while they point out to assurance offices, and other companies trading in pecuniary adventures on life, the perilous nature of such risks when connected with the lives of intemperate persons, and the urgent necessity for a high rate of premium, they will also not be without valuable influence on the social, political, and religious condition of society.

## ANALYTICAL VIEW

OF

## RAILWAY ACCIDENTS.

The unusual degree of public attention recently directed to the nature, cause, and extent of railway accidents, has induced me to submit the present paper to the consideration of the public. The vital importance of the railway system to the commercial and social interest of this country, and its rapidly increasing magnitude, threatening to absorb every other means of intercommunication, render an investigation into the causes of accidents in railway traffic, and their effect on the loss of life and limb, one of no ordinary importance.

In order to accomplish as complete an analysis as possible of what will immediately appear to be a very complicated question, there has been embraced in the present inquiry the whole of the information contained in the documents issued by the Railway Department of the Board of Trade, from the 7th of August, 1840, until the most recent return, which brings the results down to the 1st of January, 1853.

Before entering into the inquiry as to the nature of accidents, it will be necessary to understand the extent of railway communication, and the degree to which the public have availed themselves of it.

The following Table shews the number of miles open for traffic at various dates since the month of August, 1840:—

TABLE I.

| DATE.               | Miles open to Traffic. | Periodical Increase of Railway Communication. |
|---------------------|------------------------|-----------------------------------------------|
| August, 1840        | 1,330                  | Miles                                         |
| 31st December, 1840 | 1,556                  | 226 (increase of 5 months).                   |
| ... 1841            | 1,717                  | 161 (increase of 1 year).                     |
| ... 1842            | 1,857                  | 140 ...                                       |
| ... 1843            | 1,952                  | 95 ...                                        |
| ... 1844            | 2,148                  | 196 ...                                       |
| 30th June 1845      | 2,343                  | 195 (half-yearly).                            |
| ... 1846            | 2,765                  | 422 (increase of 1 year).                     |
| ... 1847            | 3,603                  | 838 ...                                       |
| ... 1848            | 4,478                  | 875 ...                                       |
| ... 1849            | 5,447                  | 969 ...                                       |
| ... 1850            | 6,308                  | 861 ...                                       |
| ... 1851            | 6,698                  | 390 ...                                       |
| ... 1852            | 7,076                  | 378 ...                                       |
| 31st December, 1852 | 7,336                  | 260 (half-yearly).                            |

From the third column of the above Table, it will be seen that the five years immediately succeeding the 30th of June, 1845, were a period of the greatest activity in the construction of railways, nearly 4000 miles having been opened for traffic in that time, or upwards of one-half of the whole extent of railway communication. The maximum extent of railway opened for traffic in any one year was in 1849; since then much less activity has prevailed, and the number of miles opened has gradually declined every year down to 1852. However satisfactory this activity and energy in developing the railway system may appear, it still contrasts very disadvantageously with the progress of our neighbours in the United States of America. From the seventh census, printed by order of the House of Representatives, it appears that

ABSTRACT A.

|                             | Number of Miles open to Traffic. | Number of Miles in Progress. | Total Miles. |
|-----------------------------|----------------------------------|------------------------------|--------------|
| On the 1st of January, 1852 | 10,843                           | 10,898                       | 21,741       |
| On the 1st of January, 1853 | 13,266                           | 12,681                       | 25,947       |
| Increase in 1 year          | 2,423                            | 1,783                        | 4,206        |

This active spirit of railway extension is not confined to one or two of the States; but appears to be, to a greater or less extent, characteristic of at least twenty-one of them.

The following Table contains a large amount of information on the extent of passenger traffic on the railways of this country; viz:—

- (a.) The average fare per mile for each class of passengers for each year since the 7th of August, 1840.
- (b.) The number of passengers of each class who travelled during each year.
- (c.) And the amount of money received for passenger traffic from each class during each year.

\* All Classes is not the total of the four preceding columns, but includes Mixed Trains, and also Holders of Periodical Tickets.

From the above Table it appears that, in the year ending the 30th June, 1842, the total number of passengers travelling by railways was 19,000,000; but in the year ending the 30th of June, 1852, just ten years after, the number of passengers was no less than 86,758,997, being an increase of about 357 per cent., while, in the same ten years, the number of miles of railway in operation had increased from 1787 miles to 7076 miles, being an increase of nearly 296 per cent., so that the passenger traffic has increased to a much greater extent than the lines of railway communication.

With respect to the revenue from passenger traffic on railways, it is remarkably curious to observe the fluctuations in the receipts from the different classes. The parliamentary trains cannot be considered to have been in proper operation prior to the years 1846-7; and since then the following very striking fluctuations in the passenger traffic of each class manifests itself:—

## ABSTRACT B.

| In the Year ending the                                           | The Number of Passengers by the |                |                 |                      |
|------------------------------------------------------------------|---------------------------------|----------------|-----------------|----------------------|
|                                                                  | First Class.                    | Second Class.  | Third Class.    | Parliamentary Class. |
| 30th June, 1847 . . . . .                                        | 6,572,714                       | 18,699,288     | 15,865,310      | 6,985,493            |
| 30th June, 1852 . . . . .                                        | 10,143,442                      | 30,967,913     | 15,642,137      | 29,973,553           |
| Increase of Traffic per annum }<br>in the above five years . . } | 3,570,728                       | 12,268,625     | — 223,173       | 22,988,060           |
| Or, an Increase in each Class of                                 | 54·3 per cent.                  | 65·6 per cent. | — 1·4 per cent. | 329·1 per cent.      |

It thus appears that, while there has been a pretty uniform rate of increase in the first and second classes, of 54·3 per cent. and 65·6 per cent. respectively, there has been actually a slight decrease in the number of passengers travelling by the third class carriages; in fact, it will be seen from the figures in Table II preceding, that ever since the year 1846, the number of passengers travelling by third class carriages has been very uniform, notwithstanding that the line of railway communication has since then increased 156 per cent., the greatest number, in any one year, being 16,990,073, in 1851, and the least being 14,378,376, in 1849; but, viewed in connection with this, will be seen the wonderful increase in the number of persons travelling by the parliamentary trains: ranging from 6,985,493, in 1847, to no less than 29,973,553, in the year 1852, being an augmentation of 329·1 per cent. This very remarkable result in the increase of passengers by the parliamentary trains will be hereafter referred to; but it is now necessary to direct attention to the receipts from each of these classes.

## ABSTRACT C.

| In the Year ending the                                    | Receipts from the |                |                 |                      |
|-----------------------------------------------------------|-------------------|----------------|-----------------|----------------------|
|                                                           | First Class.      | Second Class.  | Third Class.    | Parliamentary Class. |
| 30th June, 1847 .....                                     | £<br>1,675,759    | £<br>2,048,080 | £<br>737,452    | £<br>539,977         |
| 30th June, 1852 .....                                     | 2,389,971         | 3,010,921      | 662,230         | 1,809,163            |
| Increase of Receipts yearly<br>in the above 4 years ..... | 714,212           | 962,841        | —75,222         | 1,269,186            |
| Or, an Increase in each<br>Class of .....                 | 42·7 per Cent.    | 47·0 per Cent. | —10·2 per Cent. | 235·00 per Cent.     |

These results follow in somewhat the same order as those deduced in Abstract B, with regard to the number of passengers; but a further abstract of the facts furnished in Table II, is calculated to throw some additional light on the increase of receipts in recent years from the parliamentary trains.

## ABSTRACT D.

| During the Years | Average Fare per Mile, in Pence. |               |              |                      |
|------------------|----------------------------------|---------------|--------------|----------------------|
|                  | First Class.                     | Second Class. | Third Class. | Parliamentary Class. |
| 1840—43          | 2·506                            | 1·809         | 1·261        |                      |
| 1844             | 2·349                            | 1·699         | 1·145        |                      |

| 1847             | 2·046                            | 1·414         | ·877         | ·905                 |
| 1848             | 2·089                            | 1·695         | ·953         | ·939                 |
| 1849             | 2·217                            | 1·614         | ·982         | ·952                 |
| 1850             | 2·183                            | 1·584         | ·951         | ·933                 |
| 1851             | 2·103                            | 1·531         | ·929         | ·913                 |
| 1852             | 2·126                            | 1·550         | 1·023        | ·905                 |

From this Abstract it will be seen that, in the first and second classes, the minimum rate of fares was charged in the years 1846–7, until which period the scale of charges pretty uniformly and gradually decreased; but since then they have fluctuated at considerably higher prices, and have recently shewn a very decided tendency to increase.

It may be interesting to observe in this place, the difference in the rates of fares charged in different parts of the kingdom. The form of the returns of the railway department do not admit of this being done prior to the year 1850; and the following figures embrace, therefore, only the three years 1850–2:—

| Place.              | Average Fare per Mile during 1850—52, in Pence. |               |              |                      |
|---------------------|-------------------------------------------------|---------------|--------------|----------------------|
|                     | First Class.                                    | Second Class. | Third Class. | Parliamentary Class. |
| England and Wales . | 2·257                                           | 1·567         | 0·983        | ·916                 |
| Scotland . . . . .  | 2·022                                           | 1·565         | 1·120        | ·936                 |
| Ireland . . . . .   | 1·698                                           | 1·298         | 0·751        | ·844                 |

These results are calculated to throw some light on this branch of railway management. In Ireland, it will be seen, the fares are for every class less than in either England or Scotland. What is also worthy of remark is, the fact that in Ireland the fares for every class of passengers have, during the above three years, been uniformly decreasing, the rates, in 1852, being about 5 per cent. less in the first, and 8 per cent. less in the parliamentary class than they were in 1850. In Scotland, on the other hand, there has, in the same period, been a decided increase of fares in every class; while in England the fares in the second and third classes only, have increased. If the object of this paper admitted of an extension of this part of the inquiry, it would be important to trace the connection of cheap fares and the fluctuations in the passenger traffic. The scale of fares on the Scotch lines is very peculiar. The first-class fares are intermediate between those for England and Ireland; the second class almost precisely the same as on the English lines, but quite 20 per cent. higher than those on the Irish lines; the third class fares are 14 per cent. above the English, and 49 per cent. above those of the Irish lines; and the parliamentary trains charge fares 2 per cent. above those of the English, and 11 per cent. above those of the Irish railways.

It is, however, in the parliamentary trains that the evident advantages and effects of cheap travelling are to be witnessed. Nothing can be more conclusive on this head than the facts contained in Abstracts B and C; for if any evidence were wanted of the adaptation of the railway system to the locomotive necessities of the population of this country, it is furnished in the magical effects which the cheap and convenient parliamentary trains, stopping at every station, have had on the amount of passenger traffic since the years 1846–7, and the consequent increase of revenue to railway companies. But the introduction of parliamentary trains shews a still more wonderful result on the passenger traffic of recent years, and of a character but very imperfectly understood even by those supposed to be giving attention to railway matters. This interesting feature will be seen in the following table, in which will be found for each year—

- (a.) The total mileage of each class of passengers, deduced from the data contained in Table II.
- (b.) The average distance, or number of miles, travelled by passengers in each class; also
- (c.) The average distance travelled by all classes of passengers taken collectively; and,
- (d.) Finally, the total distance, or number of miles travelled in the aggregate by the whole of the passengers.

TABLE III.

| Date.     | Total Mileage of each Class. |               |              |                | Average Distance Travelled by Passengers in each Class. |               |              |                | Average Distance by each Passenger without distinction of Class. | Total Distance Travelled (or Mileage) by all the Passengers collectively. |
|-----------|------------------------------|---------------|--------------|----------------|---------------------------------------------------------|---------------|--------------|----------------|------------------------------------------------------------------|---------------------------------------------------------------------------|

This Table shews that the average distance travelled by the passengers of each class is yearly becoming less and less. This is observable in a remarkable degree in the second, third, and the parliamentary classes; and also to some extent in the first class. The following Abstract gives a succinct view of these facts:—

## ABSTRACT E.

| During the Years | Average Distance in Miles travelled by Passengers in the |               |              |                      |              |
|------------------|----------------------------------------------------------|---------------|--------------|----------------------|--------------|
|                  | First Class.                                             | Second Class. | Third Class. | Parliamentary Class. | All Classes. |
| 1844 to 47       | 28·6                                                     | 17·7          | 12·5         | 20·1                 | 17·7         |
| 1848 ... 51      | 28 2                                                     | 15·7          | 11·0         | 16·4                 | 16·3         |
| 1852             | 26·6                                                     | 15·1          | 10·0         | 16·0                 | 15·8         |

The figures given in this Abstract disclose the remarkable feature connected with the introduction of cheap fares, and which, at first sight, may appear anomalous, viz., that of passengers by the parliamentary trains, travelling greater distances than those by either the second or third class carriages. An examination, however, of the facts given in Table II, with regard to third class passengers, will help to throw some light on this result. It will be there seen that, ever since the year 1846, little or no change has taken place in the amount of the third class traffic; in fact, the obviously absurd plan in use in this country, of having four classes or grades of passengers, has had the effect of almost neutralizing the third class and substituting the parliamentary; but this is evidently not the only effect which the cheap parliamentary fares have had on the character of the passenger traffic. The upper and middle classes, for whom the first and second class modes of conveyance are more particularly designed, are so circumstanced in their travelling excursions, as to be called on to go greater distances than those to whom the lower fares are a necessity. The avocations, business arrangements, and social relations of the wealthy and the middle classes are generally such as to involve the necessity of travelling to greater distances, and hence we should naturally expect the lessening average distance of each journey as shewn in Abstract E, with respect to the first, second, and third classes; but whence the amount of the increased distances travelled by the parliamentary class beyond that by either the second or third class? It will be found in the circumstance of the immense disparity between the fares of the parliamentary trains and those of the first and second class, which induces a large number of persons, going distant journies, to economise their expenses by the great saving in the prices of parliamentary trains. And this explanation will be fully understood by any one making a careful examination of the ninth column of Table II, and also the fifth column of Table III, in which it will be found, that during the year 1852 the traffic of the parliamentary class had so rapidly and so greatly increased, that

The total Mileage exceeded that of the Third Class by 324,416,156 miles.

The total Mileage exceeded that of the First Class by 209,978,861 ...

The total Mileage exceeded that of the First and  
Third Classes united by . . . . . } 54,616,984 ...

And even exceeded the total Mileage of the Second  
Class by . . . . . } 13,570,910 ...

Nothing more is needed to shew the growing importance of cheap fares, and whence arises the unexpected result of the prolonged average journeys in the parliamentary classes beyond all the other classes except the first. It might almost be affirmed, from an inspection of column 5, Table II, and the last column of Abstract D, that even railway directors are themselves beginning to understand the importance of parliamentary trains and cheap fares; for while the fares of every other class shew a very decided tendency to increase, the scale of the parliamentary class has been gradually lowering ever since the year 1849; and the legitimate consequence of this decrease in the rate of charge has been an increase of the revenue of that class, both absolutely, and relatively to the receipts from the whole passenger traffic.

#### ABSTRACT F.

| During the Years<br>ending | Amount of Revenue from |                           |                                                             |
|----------------------------|------------------------|---------------------------|-------------------------------------------------------------|
|                            | All Classes.           | Parliamentary<br>Classes. | Ratio of Receipts in Parliamentary<br>Class to all Classes. |
| 30th June, 1849 . .        | £<br>6,105,975         | £<br>1,059,786            | 17·3 per cent.                                              |
| 30th June, 1852 . .        | 7,984,652              | 1,809,163                 | 22·7 per cent.                                              |
| Increase . .               | 1,878,677              | 749,377                   |                                                             |

It thus appears, that no less than 22·7 per cent. of the whole revenue from passenger traffic arises from parliamentary fares.

Apart from their financial interest and value, some of the conclusions arising directly out of the preceding Tables and Abstracts are of immediate importance in questions hereafter arising in this paper.

1st. The fact that, while since the year 1842 the extent of railway communication has increased 296 per cent., the number of passengers has increased at the higher ratio of 357 per cent.

2nd. Although the total mileage has increased from 332,500,000 miles to no less than 1,370,792,153 miles per annum in the same period, still the average distance travelled by each passenger, taking all classes collectively, has decreased from 17·5 miles to 15·8 miles each journey; and,

3rd. Consequently, this modification in the traffic of passengers must be attended with an increased number of arrivals and departures from the various railway stations, relatively to the whole amount of passenger traffic; a

circumstance which will be found to have an important bearing on some of the results to be hereafter discussed.

Much has of late been written on the causes of railway accidents, and an endless variety of suggestions have been offered for their prevention for the future; but, almost without a single exception, the whole of what has been written, and all the remedies proposed, appear to have originated from observations on isolated, or at all events on a very partial number of cases, and nothing like a fair attempt has been made to analyse the whole of the accidents, so as to shew the numerical frequency of each kind, or its tendency to occasion loss of life or limb. Some, while urging the necessity of improvement in the use and management of signals, will be found to assume that nearly all the accidents are due to causes which the suggested improvements would remove. Others again, while adopting the same view to a greater or less extent, take for granted that the bulk of all the accidents assume the form of collisions, and not contenting themselves with the simple aid of the telegraph and other station signals, bring before the public new forms of breaks and other kindred appliances, calculated to stop, in a speedy manner, trains while in motion. These and many other modes of looking at railway accidents, may, and very likely will, lead to improvements; but still it will be found that the majority of accidents would be left untouched, and a great deal would remain to be done before anything like a considerable reduction in them is effected. From looking at so important a subject from such partial points of view, very little benefit is to be hoped; and under this conviction it has been thought necessary, prior to entering on the consideration of remedies, to ascertain, as correctly as possible, the true nature, extent, and causes of the various kinds of accidents.

A little reflection will suffice to shew that all railway accidents may be so classified as to exhibit them—

1st. In relation to causes directly connected with the state and condition of the road and permanent way; and,

2nd. As connected with the construction and management of the rolling stock, namely, engines, carriages, trucks, &c. And this last branch of the classification is susceptible of many subdivisions; for even assuming that the permanent way, locomotive machinery, and appliances, were perfect in construction and durability, a large class of accidents will be found to take place from causes involving the considerations of skill in the management of the various details of a railway and the working of trains and signals.

In the following analysis of the accidents, an attempt has been made to effect such a classification of them as would shew to what extent they were due to causes beyond the control of the respective companies; and also exhibit in what degree they were due to causes falling within the control or management of the companies.

By this mode of inquiry, results, it is hoped, will be arrived at to enable the

public either to judge how far the frequently occurring accidents are susceptible of diminution, by the exercise of greater vigilance on the part of the railway staff and the employment of greater intelligence, or, by bringing into more prominent view the defects in the construction and maintenance of the permanent way and the machinery, to suggest improvements.

In such an analysis, considerable care is needed as to the precise form or kind of cause under which the accidents should be arranged; for it is evident that the same general kind of accident might be repeated over and over again, but in a slightly modified form in regard to some of its details, thus rendering it quite possible to make many subdivisions in the general class or cause. It must, however, be obvious that subdivisions of this kind might be carried so far as to deprive the results of any practical value: unless each embraced a sufficient group of facts from which to draw conclusions, not only as to the characteristic results of that particular class of accidents, but also as to the permanency of the connecting circumstances usually giving birth to them, no importance could be attached to such minute subdivisions. In order to avoid the evils which would result from any attempt to deduce general principles from observations on a distinctive group of accidents of small numerical value in itself, several such groups have in many cases been combined, having one or more points of common agreement. Keeping considerations of this kind closely in view, and never losing sight of the urgent necessity, that the results to be arrived at should have a strictly practical bearing and application, the analysis made has recognised twelve principal causes or rather conditions under which accidents have taken place, six of which are assignable to circumstances over which the companies have no direct or certain control; the other six embracing causes which fall directly under the control of the companies, through their officers and servants.

Having thus decided on a mode of inquiry which was deemed calculated to exhibit with sufficient precision for practical purposes the causes of the various accidents, it next appeared important to adopt a separate and distinct classification of them as they affected passengers, as they affected the public not passengers for the time being, and as they affected the officers and different servants of railway companies.

As it was also of importance to determine the variations, if any, at different periods in the frequency of railway accidents from different causes, the results will be found given for each year, for each cause, and for each class of persons.

In the following eight Tables will be found a detailed record of the number of persons killed, and of the number injured, in each year since 1840, from each of twelve different causes.

Table IV has reference to passengers only.

Table V has reference to the public not passengers, very often the friends of passengers accompanying them to the station, or meeting them on arrival.

Table VI has reference to trespassers on the lines.

Tables VII—XI inclusive, relate to the employés of the companies.

TABLE IV.—Number of Deaths and Injuries from various causes among PASSENGERS.

| CAUSE.                                 | Reference No. | 1840.   |          | 1841.   |          | 1842.   |          | 1843.   |          | 1844.   |          | 1845.   |          | 1846.   |          | 1847.   |          | 1848.   |          | 1849.   |          | 1850.   |          | 1851.   |          | 1852.   |          | Total.  |          |

The following is a condensed summary of the results of the preceding eight Tables:—

## ABSTRACT G.

*Deaths and Injuries amongst Different Classes, from all Causes, from the 7th August, 1840, to the 31st December, 1852.*

| CLASS.                                | Killed. | Injured. | Ratio of Injured to Killed. |
|---------------------------------------|---------|----------|-----------------------------|
| Passengers . . . . .                  | 266     | 1,796    | 675·20 per cent.            |
| Public, by their own negligence . . . | 175     | 65       | 37·14 ...                   |
| Trespassers . . . . .                 | 306     | 84       | 27·45 ...                   |
| Engine Drivers . . . . .              | 73      | 94       | 128·77 ...                  |
| Stokers . . . . .                     | 116     | 123      | 106·04 ...                  |
| Guards . . . . .                      | 127     | 100      | 78·74 ...                   |
| Porters . . . . .                     | 117     | 65       | 55·56 ...                   |
| Other Servants . . . . .              | 648     | 321      | 49·54 ...                   |
| Total . . . . .                       | 1,828   | 2,648    | 144·86 per cent.            |

The last column of this Abstract shews in one respect a most remarkable difference in the way in which the accidents affect passengers and the servants of the companies. The number injured amongst passengers being in the ratio of 675·20 per cent. to that of the killed; but amongst railway servants, the number of injuries falls short of the number of deaths, the ratio of injuries being almost exactly 65 per cent. of the deaths. The cause of this distinction will hereafter appear.

On referring to Table II preceding, it will be found, that within the period to which the facts of the preceding Abstracts relate, the total number of passengers amounted to 615,133,727. And, consequently  $\frac{615,133,727}{266}$ , or one in every 2,312,533 passengers has been killed since the 7th of August, 1840.

And in like manner  $\frac{615,133,727}{1,796}$ , or one in every 342,502 passengers has sustained serious bodily injury in the same time. So that, if the causes which have hitherto prevailed in producing railway accidents should remain constant, the preceding ratios would measure the risk of life and limb in railway travelling.

The following Table gives the result of Tables IV to XI, in a more condensed form by omitting the causes of the accidents.

TABLE XII.  
*Total Number of Persons Killed and Injured on Railways.*

| Class.                             | 1840.   |          | 1841.   |          | 1842.   |          | 1843.   |          | 1844.   |          | 1845.   |          | 1846.   |          | 1847.   |          | 1848.   |          | 1849.   |          | 1850.   |          | 1851.   |          | 1852.   |          | Total.  |          |
|------------------------------------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|---------|----------|

| Guards . . . .                     | ..      | 2        | 1       | 5        | 7       | 2        | 5       | 2        | 5       | 6        | 6       | 7        | 9       | 9        | 10      | 9        | 22      | 10       | 15      | 14       | 21      | 15       | 14      | 3        | 12      | 16       | 127     | 100      |
| Porters . . . .                    | 1       | ..       | 4       | 3        | 3       | 2        | 8       | 4        | 6       | 4        | 6       | 2        | 7       | 7        | 12      | 4        | 10      | 6        | 13      | 8        | 9       | 5        | 19      | 11       | 19      | 9        | 117     | 65       |
| Other Servants .                   | 12      | 8        | 23      | 18       | 27      | 22       | 21      | 13       | 28      | 17       | 36      | 23       | 61      | 35       | 67      | 31       | 86      | 33       | 82      | 41       | 79      | 22       | 63      | 21       | 63      | 37       | 648     | 321      |
| Total . . .                        | 46      | 167      | 69      | 128      | 73      | 71       | 67      | 48       | 84      | 128      | 100     | 144      | 141     | 205      | 211     | 174      | 202     | 219      | 199     | 186      | 209     | 254      | 211     | 438      | 216     | 486      | 1,828   | 2,648    |

The following condensed summary of this Table, so far as passengers are affected, shews, in a very satisfactory way, the gradual diminution of railway accidents.

## ABSTRACT H.

| PERIOD. | Passengers. |         |          | Ratios.       |                |
|---------|-------------|---------|----------|---------------|----------------|
|         | Number.     | Killed. | Injured. | One killed in | One injured in |
| 1840-43 | 57,617,578  | 61      | 260      | 944,550       | 221,606        |
| 1844-47 | 156,698,002 | 68      | 370      | 2,304,382     | 423,508        |
| 1848-51 | 264,173,027 | 107     | 785      | 2,468,907     | 336,526        |
| 1852    | 86,758,997  | 30      | 381      | 2,891,966     | 227,714        |

It thus appears that, while in the years 1840-43, there was 1 killed in every 944,550 passengers, there was, in the years 1848-51, only 1 in every 2,468,907 passengers, being not one death for two which happened in the earlier period.

So also will a reduction be found to have taken place in the ratio of passengers injured.

In like manner will Table XII furnish the means by which to determine the relative number of railway servants killed and injured in the same periods; but it is proposed, in the first place, to keep to that part of the inquiry which affects the passengers only. This, although really the least important branch of the subject, so far as loss of life is concerned, is, nevertheless, that in which the general public is most interested; and, as the daily and periodical press have recently taken up the matter so warmly, as complete an analysis of it will be given in this paper as the available facts and data will admit of being accomplished. In order to carry out this view, the whole of the materials have been re-arranged in the following eight Tables, from which a very distinct and complete knowledge of the intensity of each cause in producing accidents among all the classes of persons observed upon, in each year, and throughout the whole period, may be obtained.

It will be seen from Tables XIV and XV, that the number of deaths from railway accidents among the public, not being either passengers or employés, is much greater than amongst passengers merely.

The number of passengers killed, according to Table XIII, is 266.

The number killed of the public (neither passengers nor employés), by their own negligence, and of trespassers, is 481.

But the consideration of the last group of deaths will be likewise reserved for discussion in the latter part of this communication.

TABLE XIII.

*Number of Deaths and Injuries from various causes among PASSENGERS.*

| Years.   | Collision. |          | Off Line. |          | Running into Station. |          | (d) Axle Breaking. |          | (e) Machinery Breaking. |          | (c) Falling from Train. |          | (b) Jumping from Train. |          | (f) Run over. |          | Collision at Station. |          | (a) Mounting Train in motion. |          | Crushed. |          | Miscellaneous. |          | Years.      | Total.  |          |
|----------|------------|----------|-----------|----------|-----------------------|----------|--------------------|----------|-------------------------|----------|-------------------------|----------|-------------------------|----------|---------------|----------|-----------------------|----------|-------------------------------|----------|----------|----------|----------------|----------|-------------|---------|----------|

The preceding eight Tables have been given in the present very complete form, so as to permit other inquirers who may happen to take a different view of the manner in which the subject should be treated, to make new combinations for themselves. The following Table, XXI, on next page, shews, for three different periods of years, the ratio of the mortality per cent. from each cause to the mortality from all causes; and, so far as passengers are concerned, some of the results are rather curious.

It will be seen from the first section of this Table, that the deaths of passengers from collisions, and from trains running off the line, which constitute a large portion of the whole, have been gradually diminishing, while deaths from passengers falling from the trains have scarcely varied. Again, the deaths from axles breaking, in the four years 1840-3, formed 8 per cent. of the whole deaths in that period; but, since the year 1844, not a single death of a passenger has taken place assignable to that cause. And in regard to deaths from the breaking of other parts of the machinery none have happened since 1847.

In the latter part of 1840, the death of one passenger was occasioned by the running of a train into the station; but no other since that time, although 21 have been injured from the same cause at different periods. The deaths of passengers from collisions at stations increased subsequent to 1843, and have since remained nearly uniform at about 15 per cent. of the deaths from all causes.

The deaths occasioned by passengers jumping from trains while in motion have increased in a very remarkable manner ever since 1840, as well as the deaths from passengers mounting trains while in motion.

Results of the kind now enumerated, although given in strict accordance with the methods of many statistical inquirers, are, if given in such form only, liable to a serious objection, for in every case where the intensity of a variety of causes is being measured, the pressure of any one or more of the causes might actually be remaining constant, while the form of the preceding Table is capable of making them appear as increasing or decreasing in intensity: and *vice versâ*, the intensity of the same causes might in reality be undergoing great modifications, and at the same time appear uniform in the Table. An attentive consideration of the principle on which the Table is constructed will shew this to be the case; and the actual facts contained in it furnish an excellent illustration of these remarks. It will be seen that, in the period 1848-51, no deaths have taken place among passengers from the causes placed third, fourth, and fifth in order; and the immediate effect of the exclusion of deaths from these causes is to give an apparent augmentation of intensity to the remaining causes in operation in that period; a similar effect would also be produced, although not in degree the same, by any fluctuations whatever in the intensity of one or more of the causes. The proper use of such a Table as that now under consideration, is to direct attention to the fact of disturbing causes being in operation, but not to measure the degree or the exact amount of the intensity of each cause; which must be determined by a different method.

It is not easy, in a short paper, to follow a course of argument keeping clearly in view the many fluctuations in the ratio of deaths among a great variety of causes; but it  
[is obvious

TABLE XXI.

*Ratio of Mortality per Cent. from each cause, to the Mortality from all causes, among each Class of Persons.*

| CAUSE.                             | Passengers. |          |          | Public by their own Negligence. |          |          | Trespassers. |          |          | Engine Drivers. |          |          |

| Crushed . . . . .                  | ...      | 11.91    | 10.21    | 7.70     | 6.67     | 13.89    | 37.50    | 32.26    | 35.30    | 10.84           | 6.25     | 14.51    |
| Miscellaneous . . . . .            | ...      | 19.05    | 10.21    | 38.46    | 30.00    | 23.61    | 12.50    | 12.90    | 15.69    | 2.41            | 5.21     | 15.81    |

is obvious that a number of the circumstances, under which railway accidents have taken place, are for many purposes susceptible of the very simple classification already more than once alluded to.

A large number of the deaths are assignable to causes over which it is evident the directors and managers have little, if any, control, such as—

- (a) Passengers mounting trains while in motion.
- (b) Passengers jumping from trains while in motion.
- (c) Passengers falling from trains while in motion.
- (d) Axles breaking.
- (e) Machinery breaking.
- (f) Passengers being run over.

And if all the remaining causes in the preceding Tables were placed to the credit of the management of railways, and held as coming in some measure under the control of the railway officers and servants of the companies, little exception can be taken to the classification on the ground that it is calculated to underrate their responsibilities.

The following Abstract will shew the results thus arrived at:—

#### ABSTRACT I.

| CAUSES.                                                                 | Number of Passengers. |          |
|-------------------------------------------------------------------------|-----------------------|----------|
|                                                                         | Killed.               | Injured. |
| (A) Beyond control of the Companies . . . . .                           | 119                   | 171      |
| (B) Under control of the Companies, (including miscellaneous group) . . | 147                   | 1,625    |
| Ratio per cent. of (A) to the whole . . . . .                           | 44·7                  | 9·5      |
| Ratio per cent. of (B) to the whole . . . . .                           | 55·3                  | 90·5     |

It will thus be seen, that about 44·7 per cent. of all the deaths has taken place from causes over nearly all of which the passengers themselves have control, the exception being the eight deaths included in causes (d) and (e), and for which the companies can scarcely be in any way held responsible. But in regard to the injuries, 9·5 per cent. only of the accidents are so circumstanced, which calls attention to a very remarkable feature in the results now under consideration.

- (a) The deaths from causes beyond the control of the companies form 69·6 per cent. of the number of injuries from the same causes.
- (b) The deaths from causes under the control of the companies are 9 per cent. of the number of injuries from the same causes; and

Hence the tendency of accidents, which may be considered to arise from details of management, is to inflict bodily injury rather than to occasion death; for in respect to every 100 injuries, 9 deaths take place from corresponding causes, while among the accidents due to causes within the influence of the passengers themselves, for every 100 injuries nearly 70 deaths occur.

This method of stating the results naturally leads to the inquiry, Do the accidents,

falling within the class of causes assumed to come under the control of the companies, increase or diminish?

The classification in Abstract I, it will be seen, includes the deaths of the miscellaneous groups in Tables IV to XI inclusive, and also those in Tables XIII to XX inclusive, as coming under the control of the companies; but it must be obvious, that some of these accidents will be due to causes over which the companies cannot be supposed to have any control whatever. The more correct comparison will therefore evidently be that between ascertained causes only; and the following Abstract is so corrected:—

ABSTRACT J.

| CAUSES.                        | Deaths of Passengers during |                       |            |                       |            |                       |
|--------------------------------|-----------------------------|-----------------------|------------|-----------------------|------------|-----------------------|
|                                | 1840—43.                    |                       | 1844—1847. |                       | 1848—1851. |                       |
|                                | Number.                     | Per-Centage of Total. | Number.    | Per-Centage of Total. | Number.    | Per-Centage of Total. |
| Beyond control of Companies .  | 18                          | 37·50                 | 31         | 51·67                 | 54         | 56·84                 |
| Under control of Companies . . | 30                          | 62·50                 | 29         | 48·33                 | 41         | 43·16                 |

It will thus be seen, that the deaths from causes under the control of the companies have, in reference to the total deaths from all causes, been gradually diminishing ever since 1840.

|                       |                                                                 |   |                                      |
|-----------------------|-----------------------------------------------------------------|---|--------------------------------------|
| In the period 1840—43 | } the deaths from all causes under the control of the Companies | { | = 62·50 per cent. of all the deaths. |
| ... 1844—47           |                                                                 |   | = 48·33                              |
| ... 1848—51           |                                                                 |   | = 43·16                              |

So that it is evident, that the class of accidents under the control of the several companies is decreasing in relation to the total accidents in a most satisfactory and very rapid manner.

In order to avoid the objections which might be urged against the preceding mode of comparison, prominently referred to in speaking of Table XXI preceding, the following arrangement of the facts is given, which is faultless as a test, but establishes the same conclusion arrived at from a consideration of Abstract J.

ABSTRACT K.

| CAUSES.                                         | Period of Observation. |                  |                  |
|-------------------------------------------------|------------------------|------------------|------------------|
|                                                 | 1840—43.               | 1844—47.         | 1848—51.         |
| Number of Passengers. . . . .                   | 57,617,587             | 156,698,002      | 264,173,027      |
| Deaths from Causes beyond control of Companies  | 18                     | 31               | 54               |
| Deaths from causes under control of Companies . | 30                     | 29               | 41               |
| Ratio of deaths beyond control of Companies . . | One in 3,200,977       | One in 5,054,774 | One in 4,892,093 |
| Ratio of deaths under control of Companies . .  | 1,920,585              | 5,403,379        | 6,443,244        |

There is here evidence, not only of a great diminution of all kinds of accidents to passengers, but, what is exceedingly satisfactory, of those accidents which are due to causes assumed to be under the control of the companies, in a very remarkable degree compared with the remaining class of accidents.

For while deaths from causes beyond the control of the companies have, between the periods of 1840-43 and 1848-51, diminished in the ratio of 49 to 30, those from causes under the control of the companies have diminished in the ratio of 64 to 19. This result is certainly one not generally understood by the public, for not only are all railway accidents supposed to be very much on the increase, but, those due to details of management, are believed to be rapidly and alarmingly so. The facts of the case do not support this view, for they disclose the truth, that railway management, so far as accidents producing deaths among passengers are concerned, has greatly improved, and apparently in a high and steady ratio.

|                       |                                                                |                                |               |
|-----------------------|----------------------------------------------------------------|--------------------------------|---------------|
| In the period 1840-43 | } the deaths from causes under the control<br>of the Companies | = One in 1,920,585 Passengers. |               |
| ... 1844-47           |                                                                | = ...                          | 5,403,379 ... |
| ... 1848-51           |                                                                | = ...                          | 6,443,244 ... |

So that this class of accidents has diminished to about 30 per cent. of its frequency and magnitude in the year 1843.

These results, viewed in connection with those of Abstract H, give birth to some interesting considerations. If regard be had to the causes of railway accidents, so far as they can be controlled by the companies, it is obvious that the increasing extent and complicated system of the railway communication, as it now exists in its ramified arteries over the country, together with the modifications in passenger traffic of recent years, enumerated in Clauses 1st, 2nd, and 3rd, of page 238, would, unless greatly improved management were keeping pace with the growing extent of railway traffic, lead to an immense increase in the number of accidents, not only absolutely, but relatively to the amount of that traffic.

If, therefore, the results of Abstracts H and K be borne in mind, which shew that the loss of life among passengers, from all causes, has decreased in recent years, and that at the same time, the class of deaths which have taken place from causes under the control of the companies, has, in relation to the whole of these reduced deaths, been subject, year after year, to a greatly increased rate of reduction (as shewn in Abstract K), every one, notwithstanding the present popular outcry, must be satisfied that means and influences are actively at work which are daily increasing the safety of life in railway travelling. Whether this change be due to the better general regulations enforced by the directors of the companies, or to the improved skill and intelligence of their officers and servants, still the results of this inquiry afford the most striking testimony to the recent improvement and increased safety in railway travelling; and encourage the hope that the same means will be persevered in to effect a still further reduction in the frequency and intensity of railway accidents.

An inspection of Tables XIII and XXI will shew the relative number of deaths arising from each cause; and, in regard to those accidents supposed to be under the control of the companies, the most important are those under the head of collisions and running off the line. It has been said of late, that the great bulk of all the railway accidents is due to collisions; but an inspection of Table XXI will shew that—

Collisions at stations constitute 15·0 per cent. of the whole deaths among passengers.

Other collisions, not at stations, 7·5

In all . . . . . 22·5 per cent. of the whole deaths among passengers.

When, however, we arrive at that point of this inquiry in which the rate of deaths of all classes of persons, including employés, is considered, it will be found, that of a total of 1828 deaths, not more than 119, or not one-fifteenth, has been occasioned by collisions of all sorts. Collisions do not, therefore, appear to affect railway servants so much as other causes. As they form, however, more than a moiety of all the accidents assignable to causes under the control of the companies, it may be important to view this group of casualties by itself. And the following Abstract will shew the ratio of collisions in different periods:—

#### ABSTRACT L.

| PERIOD.   | Number<br>of Passengers. | Collisions, not at Stations. |              | Collisions at Stations. |              |
|-----------|--------------------------|------------------------------|--------------|-------------------------|--------------|

| 1840—1851 | 478,488,607              | 26                           | 18,403,408   | 33                      | 14,499,655   |

An examination of the fourth and sixth columns of this Abstract shews, that even this class of accidents, on which so much importance has been placed, is rapidly diminishing in amount, the deaths by collisions at stations having, in the last period of observations above enumerated, decreased to about 58 per cent. of the ratio in the first period; and those by other collisions having actually been reduced in the most recent period to only 25 per cent. of their ratio in the earliest period. These results are of great importance; and while they are very satisfactory in shewing a diminution of deaths from all kinds of collisions, they are further practically useful in proving, that while the deaths have been reduced to one-fourth in one group of collisions, they have undergone a reduction to the extent of 42 per cent. only in the collisions at stations. This ought to awaken attention to the latter group of accidents; and those entrusted with the general superintendence of the stations should have the subject forced upon their notice.

Collisions of railway trains being one of the many causes of accidents which come so obviously under the control and management of the companies, they have been thought of sufficient importance to justify a very minute analysis of them, with the view of pointing

out the peculiar circumstances under which they usually take place, in order to be suggestive of means for their prevention for the future.

In this part of the inquiry, it has been found impossible to pursue the subject further back than the beginning of 1844; and, therefore, the observations will be confined to the nine years 1844–52 inclusive. Collisions, as may be easily supposed, take place under a great variety of circumstances; and it is often a difficult matter to arrange them under any well defined system of classification; consequently, in the following Tables, such cases only were included in the respective groups, as distinctly and unmistakeably contained some common and important characteristic, and all anomalous cases are, therefore, placed in a miscellaneous group by themselves.

Heretofore, in using the word accidents, it has meant accident to life, and has been used synonymously with “loss of life” or death; but many collisions take place unattended with fatal consequences; and, although we shall hereafter shew the loss of life consequent on each kind of collision, still it is important to discuss, in the first place, the conditions under which collisions of various kinds do take place,—therefore, in the following Table, XXII, no notice is taken of the number of persons killed and injured.

In treating of the deaths of passengers in the preceding part of this paper, it was assumed that all collisions were due to causes over which the company had control; but, in the following Table it will be seen, that of the 174 classified collisions, as many as 28 took place under circumstances which it is, to a very great degree, impossible to control, and, in fact, the collisions were of a nature, against which it would at all times be exceedingly difficult to use precautions which would effectually prevent them. They will be found in Section A of the following Table, and are all more or less accounted for by the state of the weather. Fog-signals, and some other appliances, might, in a few of these instances, be made available; but in the majority of the cases it is difficult to suggest a certain remedy.

Sections B and C of this Table may be considered to embrace collisions, the causes of which are certainly, to a very great extent, completely under the control of the companies; and it must appear to every inquirer that, of the 34 collisions in Section B, the great bulk were absolutely preventable by a sufficient amount of care. For example, of the 18 collisions enumerated in columns (*a*), (*b*), (*c*), and (*d*) of this section, 15 are due to portions of the trains becoming detached, and three to defective “breaks;” and it is difficult to conceive any sufficient reason to justify a continuance or repetition of accidents from these causes. No doubt the couplings of carriages may, under extraordinary circumstances, be found to give way, even when great vigilance has been used; but such an excuse can be of no avail in the face of so many accidents of this kind as are now under consideration, and there certainly does appear strong reason to condemn the system of management which permits a series of collisions from these causes. Again, it will be found that no less than 16 collisions took place, owing to the trains having been retarded by accidents to some portion or other of the engine. It is, no doubt, sometimes difficult to determine  
[on inspection

TABLE XXII.

*An Analysis of Causes of Collisions on Railways in Great Britain and Ireland, from 1844 to 1852 inclusive.*

| Entirely, or to a very great extent, under Control of the Companies. |                                     |                                            |                                        |                                                                              |                                                            |                                                 |                                                                                    |                |                                                            |      |             |      |      |      |      |                                     |                        |                                                                                                                 |      |      |      |

| Totals                                                               | 11                                  | 9                                          | 1                                      | 7                                                                            | 6                                                          | 5                                               | 4                                                                                  | 3              | 16                                                         | 18   | 47          | 4    | 15   | 4    | 16   | 3                                   | 5                      | 134                                                                                                             |      |      |      |

on inspection, the defects in the mechanism of an engine, still the collisions from this cause have been so many, that it is impossible to conceive that a due amount of scrutiny has been always exercised in the determination of the state of the locomotives. Greater precautions have of late years been taken to guard against this class of accidents, and greater knowledge also now exists as to what constitutes durability and efficiency in many parts of the machinery; it is, therefore, to be hoped, that still further improvements will, in these respects, yet take place, and prevent collisions from any such causes. In fact, an examination of column (*e*), Section B, of this Table is sufficient to shew, that during the last four years a marked improvement has taken place.

The collisions in the five years 1844-48, from the causes now under consideration = 10, and

In the four years 1849-52 . . . . . = 6

But in the former period, the extent of railway mileage was to that in the latter as 15,337 to 25,529, and consequently if this kind of collision had taken place in the latter period in the same ratio as in the former, the number would have been nearly 17, while, in fact, it amounted to only 6. And there appears no sufficient reason why this improvement should not continue until all such accidents, or nearly all, disappear.

The next Section, C, of this Table includes a class of collision of a most serious character, and of an alarming extent. It is, perhaps, impossible to bring any direct charge against the directors and superior officers, on account of the culpable neglect on the part of the inferior servants, to which these accidents are immediately due; but the very enormous extent of them should call forth some more effective system of supervision to enforce a faithful and certain observance of the regulations of the companies. Of the 174 collisions, of which the causes are classified in Table XXII, the extraordinary number of 104 have arisen out of what can be described as nothing but most culpable neglect.

18 are due either to the neglect or mismanagement of signals.

47 have arisen from drivers neglecting signals, and other kinds of careless driving.

4 are due to the omission of the use of the "break."

15 are owing to pointsmen neglecting their duty.

4 are owing to the neglect or carelessness of station masters. And

16 have been occasioned by the inexcusable neglect of leaving waggons and portions of trains on the line, when the same line was in use by other trains; this last cause has, however, nearly disappeared during the three years 1850-52, not more than one collision yearly having taken place.

In Section D, of the last Table XXII, it will be found that column (*c*) contains no less than 134 cases of collision, which it has been found impossible to classify in a satisfactory manner; but they are all attributable to neglect on the part of the servants of the companies.

The facts recorded in this Table are of grave importance; and, although the directors of railway companies have in recent years done an immense deal to protect passengers against loss of life and limb, they are still imperatively called on to take the subject of the frequently recurring collisions more thoroughly into consideration. When such most culpable neglect exists, as is evident by this Table, the public have a right to demand more complete protection.

The next Table to be considered is Table XXIII, which follows the same principles of classification as the Table immediately preceding, only that in addition, the number of deaths and injuries due to each kind of collision is specified, for *employés* as well as passengers.

From this Table a very clear notion may be formed of the danger to life and limb of passengers by collisions taking place from different causes. It would appear that—

|                                                                                                           |   |                           |     |     |
|-----------------------------------------------------------------------------------------------------------|---|---------------------------|-----|-----|
| (A) The 28 collisions, from causes assignable to the state of the weather, produced . . . . .             | } | 2 deaths and 69 injuries. |     |     |
| (B) The 34 collisions, from defects and breakage of machinery produced . . . . .                          |   | 11                        | ... | 208 |
| (C) The 104 collisions, arising from classified causes of neglect in railway servants, produced . . . . . | } | 21                        | ... | 305 |
| (E) And the 134 collisions arising from unclassified causes, produced . . . . .                           |   | 16                        | ... | 581 |

It hence follows, that in each of the above groups the ratios of deaths and injuries to passengers were as follows:—

|                                                                       |     |      |     |       |     |
|-----------------------------------------------------------------------|-----|------|-----|-------|-----|
| In group (A), each collision produced .071 deaths and 2.464 injuries. |     |      |     |       |     |
| ... (B),                                                              | ... | .324 | ... | 6.118 | ... |
| ... (C),                                                              | ... | .202 | ... | 2.933 | ... |
| ... (E),                                                              | ... | .119 | ... | 4.336 | ... |

And Group B, or collisions arising from defects and breakage of machinery, has evidently the greatest tendency to occasion not only death, but likewise injuries to passengers, in relation to the number of collisions. This is not quite in accordance with the features attendant on railway accidents generally, in which it will be observed that those causes usually most fatal to life are accompanied with a reduced ratio of injuries. This will appear in a strong light when the part of this inquiry, relating to *employés*, is considered.

An examination of the final columns of Table XXIII will shew that the ratio which the number of injuries bears to the number of deaths arising from collisions differs very widely from that from accidents from all causes, as exhibited in Abstract G, both as regards passengers and servants of the companies.

| Class of Accidents.                   | The Ratio of Injured to Killed. |                 |
|---------------------------------------|---------------------------------|-----------------|
|                                       | Passengers.                     | Employés.       |
| All causes in the aggregate . . . . . | 675.20 per cent.                | 65.03 per cent. |
| Collisions only . . . . .             | 2301.96 ...                     | 225.49 ...      |

It hence follows that the injuries greatly exceed the deaths amongst passengers in both of the above classes of accidents. On the other hand, the deaths amongst employés exceed the injuries from all causes in the aggregate; but in the class of collisions, the injuries, as with passengers, much exceed the number of deaths.

[Of the 308

TABLE XXIII.

*Shewing the Number of Deaths and Injuries, to Railway Employés and to Passengers, due to each cause of Collision, on the Railways of Great Britain and Ireland, from the year 1844 to the Year 1852, inclusive.*

| YEAR. | A.                                  |         |          |                         |         |          |                             |         |          |                         | The letters at the head of the columns refer to those in the Analysis of Causes of Collisions. The Accidents in col. A<sub>4</sub> would, probably, be always traceable to Neglect of Pointsmen. Those in col. D would be, in general, attributable to Neglect.—See Analysis of Causes.

A curious and very interesting analysis of railway collisions will be found in the two next succeeding Tables, XXIV and XXV.

TABLE XXIV.

*Shewing the Number of Collisions in each Year, from 1844 to 1852, inclusive, with Number of Employés and Passengers Killed and Injured thereby.*

| YEAR.  | a.<br>Passenger Trains into Passenger Trains. |           |          |             |          | b.<br>Passenger into Other Trains. |           |          |             |          | c.<br>Other into Passenger Trains. |           |          |             |          | d.<br>Other Trains into Other Trains. |           |          |             |          | Totals.               |           |          |             |          |

Of the 308 collisions recorded in Table XXIV, it will be found that—

- (a.) 48 have consisted of one passenger train coming into collision with another.
- (b.) 156 have consisted of collisions by passenger trains running into trains of another description, such as luggage, coke, mineral, contractors', &c., trains.
- (c.) 51 have been occasioned by other than passenger trains running into passenger trains. And
- (d.) 53 collisions happened by trains, not passenger trains, running into other trains, which were also not passenger trains.

It may be said, that in all the preceding four groups the public, as passengers, were interested, and even the last group, it will be found, records that three passengers were killed and six injured, although the trains were not passenger trains. These deaths and injuries took place amongst persons in charge of horses and cattle.

A very characteristic distinction in the number of collisions, under Groups (b) and (c), is observable. Group (b) shews the number of passenger trains running into others not passenger trains, while Group (c) is the converse kind of collision. Now as passenger trains usually run at a higher speed than the other trains, the greater number of collisions is occasioned by the passenger trains overtaking the others, the difference being almost exactly three times as great.

What is also somewhat curious to observe in the Table under consideration is, the rather close approximation in the number of collisions with each other of trains of a similar kind. The collisions among exclusively passenger trains were, in the nine years, exactly 48; and the collisions in the same period among trains, exclusively other than passenger trains, were 53.

The following shews the ratio of deaths and injuries among passengers in each group of collisions in Table XXIV:—

In Group (a), each collision produced .375 deaths and 6.854 injuries.

|     |      |     |      |     |       |     |
|-----|------|-----|------|-----|-------|-----|
| ... | (b), | ... | .141 | ... | 3.558 | ... |
| ... | (c), | ... | .157 | ... | 5.569 | ... |
| ... | (d), | ... | .057 | ... | 0.113 | ... |

The highest ratio of deaths, and also of injuries, in the above four combinations, will be found in Group (a); and for this there is a very obvious explanation, for the collision in this group consists of one passenger train running into another; consequently, in every such collision, taking one with another, there will be double the number of passengers exposed to risk, which will be found exposed to such risks in collisions under Group (b); and it is rather singular to find, in an inquiry of this kind, so very positive a determination to the development of a law of mortality, when so many disturbing causes might have been considered to influence the results. If the ratio of deaths and injuries in Group (a) be divided by two, the results will be, ratio of deaths .187, and ratio of injuries 3.427, not differing widely from the results of Group (b), nor from the results of Group (c), so far as regards deaths.

Another obvious and important result, arising out of this Table, is the caution indicated in regard to the position of passenger to other trains on the line; for it is the mismanagement of this detail which occasions fully one-half of the whole collisions which take place.

TABLE XXV.

*Shewing the Number of Collisions occurring to each class of Passenger Trains, as compared with those occurring to all Passenger Trains, and to each other; with the Deaths and Injuries occasioned thereby, from 1844 to 1852, inclusive.*

The next Table, XXV, gives a still further analysis of the passengers, by shewing the number of collisions to each kind of train, whether "express," "mail," "excursion," or ordinary train; and further distinguishes, among the collisions to each of these trains, the number which have resulted in injury to life or limb, and the number of collisions unattended with injury. Other than passenger-trains are excluded.

In this Table, it will be observed, that the collisions of the "express" and "excursion" trains have occasioned but one death each throughout the whole period of nine years, while the collisions of "mail" trains were not attended with a single death to a passenger. So far as collisions are concerned, this ought to satisfy the minds of the timid of the safety of travelling by quick trains.

The following is a condensed Abstract of Table XXV, in respect to passengers only:—

ABSTRACT M.

| Trains.             | Number of               |                     | Number of Passengers. |          | Ratio of Deaths and Injuries to |          |                     |          |
|---------------------|-------------------------|---------------------|-----------------------|----------|---------------------------------|----------|---------------------|----------|
|                     | Non-serious Collisions. | Serious Collisions. | Killed.               | Injured. | All Collisions.                 |          | Serious Collisions. |          |
|                     |                         |                     |                       |          | Killed.                         | Injured. | Killed.             | Injured. |
| Express . . . . .   | 3                       | 8                   | 1                     | 26       | ·091                            | 2·364    | ·125                | 3·250    |
| Excursion . . . . . | 1                       | 7                   | 1                     | 74       | ·125                            | 9·250    | ·143                | 10·571   |
| Mail . . . . .      | 8                       | 13                  | ...                   | 36       | ...                             | 1·714    | ...                 | 2·769    |
| Ordinary . . . . .  | 42                      | 173                 | 46                    | 1,032    | ·214                            | 4·800    | ·266                | 5·965    |
| Total . . . . .     | 54                      | 201                 | 48                    | 1,168    | ·188                            | 4·580    | ·239                | 5·811    |

It will thus be seen, that the ordinary trains have been fatal to life above the average. It will, however, be observed, that although the excursion trains have occasioned fewer deaths than the ordinary trains, yet the ratio of persons injured is nearly double the average. It will, likewise, be observed, that one-fifth part of all the collisions with passenger-trains are unattended with injury.

The following Table, XXVI, which includes collisions by other as well as passenger-trains, is interesting.

One remarkable feature in this Table is, the disparity in the frequency of collisions in different months of the year. It will be seen that, in the six months commencing with August and ending with January, the number of collisions is more than double of the number in the other six months of the year. This is, no doubt, to be in part accounted for by the state of the weather, as may be understood on referring to Section A of Tables XXII and XXIII; but still this would not of itself be sufficient to account for the remarkable difference observable in the preceding Table, unless it be that the "neglect," recorded in Section C of Table XXII and Section E of Table XXIII, be also to some extent occasioned by the trying nature of the weather at the same season. Another curious circumstance is the fact that in the last six months of this Table, in which double the number of collisions have taken place, not quite so many lives of passengers have been

lost, although the passenger traffic of the same six months is greater than in the other six months. For the nine years now under consideration, the passenger traffic of the first six months was 240,307,731, the passenger traffic of the second six months was 302,959,421. And, consequently, the deaths from collisions, during the first six months, were one in every 9,242,605 passengers; and, during the second six months, were one in every 12,118,577 passengers. So that those figures represent the relative chances of loss of life from collisions in railway travelling during the respective seasons, assuming that such accidents should for the future observe the same order of distribution.

TABLE XXVI.

*Shewing the Number of Collisions on the Railways of Great Britain and Ireland for the nine Years 1844—1852, for each Month of the Year, with the Number of Employés and of Passengers Killed and Injured thereby.*

| Month.                    | Number of Collisions. |                                                     |                           | Employés. |          | Passengers. |          |
|---------------------------|-----------------------|-----------------------------------------------------|---------------------------|-----------|----------|-------------|----------|

| October . . . . .         | 35                    | 8                                                   | 27                        | 8         | 18       | 4           | 102      |
| November . . . . .        | 36                    | 8                                                   | 28                        | 5         | 16       | 3           | 177      |
| December . . . . .        | 41                    | 11                                                  | 30                        | 7         | 15       | 4           | 103      |
| January . . . . .         | 28                    | 12                                                  | 16                        | 7         | 10       | ...         | 41       |
| Totals . . . . .          | 209                   | 50                                                  | 159                       | 37        | 78       | 25          | 760      |
| Totals of 12 months . . . | 308                   | 69                                                  | 239                       | 51        | 115      | 51          | 1,174    |

In respect of injuries to passengers, it will be observed, that in frequency they follow almost the precise order of the collisions themselves—the ratio to collisions in the different seasons being nearly the same. The facts in this Table are well worth examination by those intrusted with the management of Railways. It is scarcely possible to conceive that any intelligent superintendent of the trains of a railway, who thoroughly masters the facts in regard to collisions contained in Tables XXII to XXVI inclusive, could not devise some means which would prevent the recurrence of so many accidents of this class.

The only remaining Table now to be brought forward on the subject of collisions is the following one, Table XXVII, in which are shewn the places on the line at which the various collisions have taken place.

[It will be

It will be found that, of a total number of 308 collisions, no less than 110 have taken place at stations, or the very places where the greatest care and vigilance are required and might be exercised. Anything like fair attention to the use of well understood precautions, and a proper use of signals and telegraphs, should completely, or at all events to a great extent, prevent this class of accidents. The same remarks may be justly made in respect to the collisions recorded in Sections *b* and *c* of the same Table. The collisions in the first three sections of this Table constitute about 46 per cent. of the whole number, and are clearly of a kind that may be greatly diminished by a well devised system of management. The accidents from collisions on open lines, or rather at other places than stations, junctions, sidings, and crossings, amount to 165. The intensity of the different kind of collisions in this Table, in death and injury, does not exhibit any very marked disparity.

The only other important class of accidents, from which passengers suffer, and which is assumed to be under the control or management of the companies, are those occasioned by trains, or portions of trains, running off the line.

Of the 228 deaths of passengers from defined causes, given in Table XIII, it will be found that 109 are attributable to causes under control of the companies. And then, again, Table XIII shews that 35, or 32.1 per cent., were occasioned by "running off the line." So far as the management of railways is concerned in preserving the lives of passengers, this class of accidents is second in importance only to that arising from collisions. In fact, "collisions" and "running off the line" caused 91 per cent. of all the deaths of passengers for which the companies can be supposed responsible; and therefore, a thorough analysis of these two classes of accidents will complete the inquiry so far as the lives of passengers are concerned.

In the following Table, XXVIII, will be found the results of the investigation made into the immediate causes of engines, trains, and other parts of trains running off the line. The analysis will be found sufficiently minute and detailed for every useful purpose.

Of 156 cases of "running off the line," the immediate cause has been ascertained in 105 instances. And it is also found, that 105 of the accidents have been attended with injury to life and limb of passengers, and 51 resulted without any injury.

It will immediately appear on examination of Section A of the same Table, as was remarked in regard to the similar section of the Tables of collisions, that it is impossible to hold the companies responsible for every one of this group of accidents. They are so clearly due to causes difficult to be foreseen, that they may for the present be passed over as such.

But in regard to Section B, which includes none but cases of running off the line from the breaking of machinery, there can be no doubt that greater precautions might

*An Analysis of the Causes of Engines, Trains, or Parts of Trains, running off the Rails, on Railways in Great Britain and Ireland; from the Year 1844 to the Year 1852, inclusive.*

[illegible]

generally be taken. The remarks offered on the "breaking of machinery," as the immediate cause of collisions, apply with equal force in this instance, and need not again be repeated; but it is certainly to be lamented that, of the 105 ascertained cases of "running off the line," no less than 43 should be due to the "breaking of machinery." Frequent inspection by competent parties is the protection against this group of accidents: and strong measures should be enforced to secure the safety arising from this sort of supervision.

The accidents arising from the causes recorded in Section C are certainly, at least to a very great extent, preventable. Nothing but the most culpable indifference to the public safety can permit a continuance of this group of accidents, which forms upwards of 28 per cent. of all the classified accidents in the Table.

The accidents included in Columns 2 and 3 of Section D, cannot in general be attributable to negligence of the companies.

The four cases in Section E are due to reckless driving.

Sections B and C of this Table should be well considered by railway directors.

The next, Table XXIX, will shew how the various groups of accidents of "running off the line" affected life and limb of passengers.

What is strange in the record of accidents contained in this Table is, that the 51 cases, included in Sections A and B, did not occasion a single death of a passenger, while the 30 in Section C, attributable to defects in the "permanent way," produced eight deaths of passengers.

The number of deaths of passengers from obstructions on the line was three, but no passenger lost his life under Section E, through reckless driving, or excessive speed.

The miscellaneous group, Section F, it will be seen, includes 55, or upwards of one-third of all the cases of trains running off the rails, to which unascertained causes nearly one-half of the whole deaths of passengers from running off the line is due. But the returns of the railway department were either defective as to these cases, or the accidents themselves were of so peculiar a kind as not to admit of a satisfactory classification.

When that part of the subject, which has reference to the manner in which railway accidents have affected the employés, is considered, the effects of trains running off the line will be more fully discussed. From Tables XXIV and XXVI, preceding, it will be observed that collisions killed an equal number of employés and passengers; but the cases of running off the line have relatively, as will be seen by the last columns of Table XXIX, a much more fatal effect on the servants of the companies.

TABLE XXIX.

Reviewing the Number of Deaths and Injuries, to Railway Employés and to Passengers, due to each Cause of Trains, or Parts of Trains, or Engines running off the Rails of Railways in Great Britain and Ireland, from 1844 to 1852.

| A.       |  |       |  |                   |  |         |  |             |  | B. Machinery Breaking. |  |                              |  |                   |  |            |  |          |  | C. Defects in Permanent Way.    |  |       |  |                               |  |         |  |            |  | D. Obstructions on Line. |  |                         |  |                   |  |                         |  |          |  | E. Reckless Driving, or Excessive Speed. |  |       |  | F. Miscellaneous, and not ascertained. |  |         |  | Grand Total. |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  |         |  |          |  |      |  |       |  |                   |  | In the preceding Table, XXX, will be seen in what manner the different kind of trains were affected by the class of accidents now under consideration.

It was found in Table XXV that the passengers by "express" trains suffered less from the collisions which occurred, than the passengers by other trains. But in regard to the class of accidents in the preceding Table, the case is very different; for, from the 18 cases of "running off the line" by express trains, 4 deaths of passengers happened, while from the 93 cases taking place among "mail" and other passenger trains, the number of deaths was 17. In regard, however, to injuries only, the ratio was also less in the case of "express" trains.

The preceding portion of this paper has been confined chiefly to an examination of the manner in which railway accidents have affected passengers, although the Tables themselves contain the results of the analysis for employés and other persons not passengers for the time being: it now remains to investigate the manner in which railway accidents have affected railway servants, and other persons not passengers.

Although the general public is naturally most alive to the manner in which passengers suffer from accidents, still every earnest inquirer must at once sympathize with the dreadful amount of accidents and fearful loss of life to which the servants of railway companies are exposed. It is quite impossible not to regard this latter branch of the inquiry as really the more grave and important of the two. Table XII shews that while in the twelve years ending 1852 the loss of life amongst passengers was 266, 1081 deaths took place amongst the employés. This statement is of itself sufficient to prevent the remaining portion of this paper from being regarded with indifference.

Some difficulty was experienced in the treatment of the succeeding part of this inquiry, owing to the obscurity which obtained as to the precise number of persons employed in different departments of the railway service during the earlier years to which the investigation relates. Since 1848, however, several parliamentary returns afford the means of making a near approximation to the number of persons employed in the different departments, and hence offer a ready means by which to determine the numbers constantly exposed to the risk of accidents.

From the data in the following Table, XXXI, these numbers are easily deduced.

The returns which furnish the data for the last two columns of this Table were issued subsequently to the preparation of the principal part of this paper; but it will be found that the principle on which the Table has been constructed produces results almost identical for practical purposes with those given in the parliamentary returns themselves.

Table XXXII exhibits the number of employés of different descriptions exposed continuously to the risk of accidents. The principle on which it has been constructed from the data contained in Table XXXI is obvious.

[By the aid

TABLE XXXI.

*Number and Description of Persons Employed on all Railways open for Traffic in Great Britain and Ireland.*

| 30th June, 1849, to<br>30th June, 1850       | 7,894                        | 1,943¾             | 2,000    | 1,786½  | 11,222½            | 1,621½                 | 1,530¾                 | 8,622½   | 5,532½                   | 14,224½           | 1,489¾                     | 43,514½                              | 101,381½ |
| 30th June, 1850, to<br>30th June, 1851       | 8,702                        | 2,153½             | 2,258    | 2,096¾  | 12,049½            | 1,783¾                 | 1,576½                 | 9,391½   | 5,580¾                   | 14,614¾           | 1,457¾                     | 45,764¾                              | 107,429  |
| 30th June, 1851, to<br>31st Dec., 1851       | 4,755                        | 1,181½             | 1,258    | 1,203½  | 6,438              | 973                    | 811                    | 5,080    | 2,814½                   | 7,502½            | 713                        | 24,007½                              | 56,737½  |
| (Col. 8, Table XXXI.)<br>Totals—3½ years ... | 28,330+                      | 7,080              | 7,360½   | 6,659½  | 40,521             | 5,711½                 | 5,840½                 | 31,041   | 18,957                   | 50,551            | 4,777                      | 154,682½                             | 361,511½ |

The numbers in this Table are thus obtained (see Table XXXI):—

$$+ \text{Average number from 30th June, 1848, to 30th June, 1849,} = \frac{6,468 + 7,490}{2} = 6,979$$

$$\dots \dots \dots 1849, \dots \dots 1850, = \frac{7,490 + 8,298}{2} = 7,894$$

$$\dots \dots \dots 1850, \dots \dots 1851, = \frac{8,298 + 9,106}{2} = 8,702$$

$$\dots \dots \dots 30\text{th June, to 31st December, 1851,} = \frac{9,106 + 9,914^*}{4} = 4,755$$

$$\text{Total } 28,330$$

\* 9,914, number employed at end of year (from 30th June).

For, increase in half-year =  $(9,510 - 9,106) = 404$ ,

∴ ... whole year = 808.

| ... 1852 . . . . .                | 53,897          | 63      | 37       | 856           | 1,457          |
| Grand Total . . . . .             | 353,880         | 648     | 321      | 546           | 1,102          |

By the aid of Tables XXXI and XXXII, Table XXXIII has been calculated, so as to shew for precisely the same periods of time to which the data given in the early part of this paper relate, the number of employés exposed to risk; thus placing the different elements entering into the inquiry in a fitting shape to determine the relation of the one to the other. The mode by which these figures have been obtained from Tables XXXI and XXXII, will be at once understood on a careful perusal. Table XXXIII will be found exceedingly useful for future reference by those giving attention to the economics of our railway system generally, as well as to those who may direct their attention to the special object of this inquiry.

Table XXXIV completes the principal series of elementary facts which enter into the present part of this investigation. The details as to deaths and injuries will be found in Table XII, page 246 *ante*; and those in regard to the numbers exposed to the risks of accident will be found, as already stated, in Tables XXXI, XXXII, and XXXIII, preceding.

It will frequently be necessary to refer to the facts set forth in Table XXXIV; but, for the immediate purpose of determining the ratio of deaths and injuries from all causes or kinds of railway accidents amongst employés, compared with the ratio found to prevail amongst passengers, Table XXXV will be convenient; from which it will be seen that the ratio of deaths per annum amongst different classes of employés for the whole period of years, now under consideration, has been as follows, viz.:—

|                                     |     |                |            |
|-------------------------------------|-----|----------------|------------|
| The ratio of deaths per annum among |     | Engine-Drivers | = 1 in 220 |
| ...                                 | ... | Stokers        | = ... 144  |
| ...                                 | ... | Guards         | = ... 117  |
| ...                                 | ... | Porters        | = ... 602  |
| ...                                 | ... | Other Servants | = ... 546  |

It is thus evident that, for the whole period from 1840-52, the ratio of deaths has been, amongst the first three classes of servants, least in the group engine-drivers, and highest in that of guards. A similar result appeared also in Table XXXIV. This relation, however, of the mortality from accidents has not been uniformly maintained by the same three classes throughout the whole of the period under observation, as will be seen by a comparison of the mortality of stokers with that of guards for the period 1844-48. The mortality of the fourth and fifth groups of employés differs widely from that of the other three groups; and the same remark is applicable to the ratio of injuries in the same groups.

|                                   |     |                |             |
|-----------------------------------|-----|----------------|-------------|
| The ratio of injuries being among |     | Engine-Drivers | = 1 in 171  |
| ...                               | ... | Stokers        | = ... 136   |
| ...                               | ... | Guards         | = ... 149   |
| ...                               | ... | Porters        | = ... 1,083 |
| ...                               | ... | Other Servants | = ... 1,102 |

In respect to deaths, the ratio for stokers was intermediate between that for engine-drivers and guards; but so far as injuries are concerned, the ratio for stokers is higher than that for either guards or engine-drivers.

It will assist the object of this inquiry to consider the facts of the preceding Table, as given in the following condensed summary:—

## ABSTRACT N.

| Period.                 | Engine Drivers, Stokers, and Guards. |         |          | Ratios.       |                |
|-------------------------|--------------------------------------|---------|----------|---------------|----------------|
|                         | Number.                              | Killed. | Injured. | One Killed in | One Injured in |
| 1840 to 1843 . . . . .  | 6,080                                | 27      | 48       | 229           | 129            |
| 1844 ... 1847 . . . . . | 10,852                               | 100     | 110      | 109           | 99             |
| 1848 ... 1851 . . . . . | 23,454                               | 148     | 116      | 158           | 200            |
| 1840 to 1851 . . . . .  | 40,386                               | 275     | 274      | 147           | 148            |
| 1852 . . . . .          | 7,252                                | 41      | 43       | 177           | 169            |
| Grand Total . . . . .   | 47,638                               | 316     | 317      | 151           | 150            |

| Period.                 | Porters and Other Servants. |         |          | Ratios.       |                |
|-------------------------|-----------------------------|---------|----------|---------------|----------------|
|                         | Number.                     | Killed. | Injured. | One Killed in | One Injured in |
| 1840 to 1843 . . . . .  | 54,134                      | 99      | 70       | 547           | 773            |
| 1844 ... 1847 . . . . . | 96,548                      | 223     | 123      | 433           | 785            |
| 1848 ... 1851 . . . . . | 209,000                     | 361     | 147      | 579           | 1,422          |
| 1840 to 1851 . . . . .  | 359,682                     | 683     | 340      | 527           | 1,058          |
| 1852 . . . . .          | 64,619                      | 82      | 46       | 788           | 1,405          |
| Grand Total . . . . .   | 424,301                     | 765     | 386      | 555           | 1,099          |

This Abstract presents facts of a very remarkable nature when compared with those given in Abstract H, page 247 *ante*. In the preceding Abstract, it will be seen that, in the first group of employés, consisting of engine-drivers, stokers, and guards, the numbers of injuries and deaths are almost identical, while amongst passengers (see Abstract O) the ratio of injured to killed was 675·20 per cent.

In regard, however, to the group consisting of porters and other servants, the number killed has been 1 in 555, and the number injured has been 1 in 1,099; or the ratio of injured to killed about 50·46 per cent.

In this way of looking at the question, some results are disclosed, which merit very serious consideration.

## ABSTRACT O.

| Class.                                        | Numbers. |          | Ratio of Injured to Killed. |
|-----------------------------------------------|----------|----------|-----------------------------|
|                                               | Killed.  | Injured. |                             |
| Engine Drivers, Stokers, and Guards . . . . . | 316      | 317      | About equal                 |
| Porters and Other Servants . . . . .          | 765      | 386      | 50·46 per cent.             |
| Passengers . . . . .                          | 266      | 1,796    | 675·20 ...                  |

There appears in this Abstract a very curious law, but one which, on reflection, is quite consistent with the circumstances known to influence the risk to which each class of persons is exposed. By viewing, in connection with the preceding results, some of the facts set forth in Abstract O, the following conclusions are arrived at:—

ABSTRACT P.

| Class of Persons exposed to Risk.             | Numbers. |          | Ratio of the Injured to Killed. |
|-----------------------------------------------|----------|----------|---------------------------------|
|                                               | Killed.  | Injured. |                                 |
| Trespassers . . . . .                         | 306      | 84       | 27·45 per cent.                 |
| Public by their own negligence . . . . .      | 175      | 65       | 37·14 ...                       |
| Other Servants . . . . .                      | 648      | 321      | 49·54 ...                       |
| Porters and other Servants . . . . .          | 765      | 386      | 50·46 ...                       |
| Porters . . . . .                             | 117      | 65       | 55·56 ...                       |
| Engine-Drivers, Stokers, and Guards . . . . . | 316      | 317      | About equal                     |
| Passengers . . . . .                          | 266      | 1,796    | 675·20 ...                      |

A very slight consideration of the nature of the circumstances, under which the accidents take place in each of the above classes, will at once explain the great disparity between the ratio of the killed and injured. If the different circumstances in which the two classes of trespassers and passengers be contrasted, it will at once appear that, in the event of an accident occurring, the chances of its proving fatal differ widely in the two groups; the former being injured principally by trains overtaking them while in motion, and consequently the probability of the accident proving fatal is very great; but, in regard to the latter, it has been shewn in Table IV, that the bulk of accidents to passengers take place under circumstances of a much less violent nature, in which the tendency to be fatal is quite inconsiderable compared with the accidents to which trespassers are liable. Of the 297 fatal accidents by defined causes to trespassers recorded in Table VI, no less than 268 are assignable to the cause "run over;" while, of the 228 fatal accidents to passengers, 99, or 43·42 per cent., have been occasioned by collisions of trains, and trains running off the line. Accidents of this kind, it will be found, are of a less violent nature than any other, and have, therefore, less tendency to be fatal; and if these facts be kept distinctly in view, the great disparity in the relative fatality of accidents in different classes, as shewn in Abstract P, will be readily understood. The following illustration of the tendency of different classes of accidents to prove fatal, so far as passengers are concerned, may be interesting and instructive on this point of the inquiry:—

## ABSTRACT Q.

*Ratio amongst Passengers of Injured to Killed from different causes.*

| Causes.                                                 | Killed. | Injured. | Ratio of Injured to Killed. |
|---------------------------------------------------------|---------|----------|-----------------------------|
| Collisions, running off line, and collision at stations | 99      | 1,505    | 1520·20 per cent.           |
| All other defined causes . . . . .                      | 129     | 230      | 178·29 ...                  |

Accidents from the last group of causes, it will be seen, are of a much more fatal character than those in the first group; and an inspection of the causes, included in the last of the above groups, will shew that they are of a kind more in common with those which affect railway servants in general, than the causes contained in the first group; and hence the explanation of the disparity exhibited in Abstract P preceding.

Abstract R gives a succinct view of the liability of different classes of persons to be injured by accidents from various causes, and also the chances of those accidents proving fatal; and it will be seen, that, in the following classes, the great bulk of the accidents take place under circumstances in which the cause of injury is of a very violent nature, and can, with few exceptions, be scarcely otherwise than fatal:—

|                           |                                          |                 |                                                |
|---------------------------|------------------------------------------|-----------------|------------------------------------------------|
| Of all the deaths amongst | Trespassers . . . . .                    | 90·24 per cent. | } Have occurred from being run over by trains. |
|                           | Public by their own negligence . . . . . | 88·66 ...       |                                                |
|                           | Other Servants . . . . .                 | 61·50 ...       |                                                |
|                           | Porters . . . . .                        | 30·39 ...       |                                                |

Again, it will be seen, that, in the following classes of the accidents also taking place under circumstances likely to be fatal:—

|                     |                |                 |                                                                                |
|---------------------|----------------|-----------------|--------------------------------------------------------------------------------|
| Of the deaths among | Engine-Drivers | 46·03 per cent. | { Are caused by "Running off the Line" and "Falling from Train."               |
| ...                 | Stokers        | 52·96 ...       | "Running off Line," "Falling from Train," and "Crushed."                       |
| ...                 | Guards         | 82·21 ...       | { "Falling from Train," "Mounting Train in Motion," "Run over," and "Crushed." |
| ...                 | Porters        | 70·58 ...       | "Run over" and "Crushed."                                                      |

These facts are sufficient to account for the tendency of different kinds of accidents, as they affect different classes of persons, to prove fatal. In Abstract Q, it will be found, that accidents to passengers from "collisions," "running off the line," and "collisions at stations," were much less fatal than those taking place from other causes; so also will it be found that, amongst the three important classes of railway servants, engine-drivers, stokers, and guards, the accidents from the same three causes are much less fatal than those from other causes.

## ABSTRACT R.

*Number of Deaths from each cause amongst different classes, also the Ratio of Deaths from each cause to the Total Deaths from all causes for the whole period, 1840-52.*

| Cause.                             | Passengers.    |        | Public by their own Negligence. |        | Trespassers.   |        | Engine-Drivers. |        | Stokers.       |        | Guards.        |        | Porters.       |        | Other Servants. |        |
